Phosphorylation of Pyruvate by the Pyruvate Kinase Reaction and Reversal of Glycolysis in a Reconstructed System*

I. KRIMSKY

From the Division of Nutrition and Physiology, The Public Health Research Institute of the City of New York, Inc., New York, New York

(Received for publication, July 30, 1958)

Lardy and Ziegler (1) obtained synthesis of phosphoenol pyruvate from pyruvate and adenosine triphosphate by reversal of the pyruvate kinase reaction. A possible mechanism was thus demonstrated for the initial step in the synthesis of glycogen from pyruvate. The amounts of phosphoenol pyruvate synthesized were, however, small, and it is rather widely held that reversal of the pyruvate kinase reaction leading to net synthesis of phosphoenol pyruvate in vivo is insignificant (2-5).

It is the purpose of this paper to report the synthesis of relatively large amounts of phosphoenol pyruvate in an enzymatic system similar to that of Lardy and Ziegler. They used muscle extracts to generate ATP by the oxidative phosphorylation of glyceraldehyde 3-phosphate; the enolase reaction was blocked with fluoride. It was found that substitution of the muscle extracts by purified glycolytic enzymes resulted in much higher steady state concentrations of PE. Synthesis of PE by reversal of the pyruvate kinase reaction was also obtained when respiring mitochondria were used as the ATP generator. Supplementation of this system with glycolytic enzymes led to formation of fructose-DP and other glycolytic intermediates.

**EXPERIMENTAL**

**Enzyme Preparations**—Phosphoglycerate mutase, phosphoglycerate kinase, enolase, and pyruvate kinase were prepared as described in the preceding paper. Glyceraldehyde-3-P dehydrogenase from muscle was prepared by the method of Cori et al. (6) and from yeast by the method of Krebs et al. (7); the extracting medium used in preparing both dehydrogenases contained 2 mg. per ml. of ethylenediaminetetraacetate. Mannitol was used instead of sucrose because contamination of some yeast enzyme preparations with invertase (which catalyzed glucose formation) and hexokinase led to net esterification of P,i.e. glucose 6-phosphate formation, without the addition of pyruvate as a phosphate acceptor.

In experiments in which mitochondria were used to generate ATP for pyruvate phosphorylation, incubation was for 30 minutes at 27°C in 20-ml. beakers shaken at about 2 cycles per second in a Dubnoff metabolic shaking incubator (Precision Scientific Company, Chicago, Illinois); deproteinization was by addition of 0.1 volume of 25 per cent trichloroacetic acid. Zero time controls were obtained by adding all the reagents directly to a solution of trichloroacetic acid.

**Reagents**—2,3-Diphosphoglycerate was prepared as described in the preceding paper; potassium pyruvate was prepared by the method of Korkos et al. (11).

**Analytical Methods**—PE and PE were determined as described in the preceding paper.

*This work was supported by Grant No. C-3463 from the National Institutes of Health, United States Public Health Service, Bethesda, Maryland.

1 The abbreviations used are: PE, phosphoenol pyruvate; fructose-DP, fructose 1,6-diphosphate; Pi, inorganic orthophosphate.

3-Phosphoglycerate was measured by oxidation of DPNH in the presence of ATP, Mg++, phosphoglycerate kinase, and glyceraldehyde-3-P dehydrogenase (12); dihydroxyacetone phosphate by oxidation of DPNH with a-glycerophosphate dehydrogenase (13); fructose-DP by oxidation of DPNH with aldolase and a-glycerophosphate dehydrogenase (13); pyruvate by oxidation of DPNH with lactate dehydrogenase (13); and a-glycerophosphate by the method of Bluett and Kennedy (14).

ATP and ADP were assayed by the method of Bowen and Kerwin (15) after removal of Mg++ from the trichloroacetic acid filtrates of reaction mixtures by passing them through a column of Dowex 50-X2, H+ form. Removal of Mg++ is necessary since it interferes with the subsequent assay.

**Mitochondrial Preparations**—These were made from rat liver by the method of Hogeboom (16) except that the suspending medium used was 0.25 M mannitol containing 1 mg. per ml. of ethylenediaminetetraacetate. Mannitol was used instead of sucrose because contamination of some yeast enzyme preparations with invertase (which catalyzed glucose formation) and hexokinase led to net esterification of Pi, i.e. glucose 6-phosphate formation, without the addition of pyruvate as a phosphate acceptor.

In experiments in which mitochondria were used to generate ATP for pyruvate phosphorylation, incubation was for 30 minutes at 27°C in 20-ml. beakers shaken at about 2 cycles per second in a Dubnoff metabolic shaking incubator (Precision Scientific Company, Chicago, Illinois); deproteinization was by addition of 0.1 volume of 25 per cent trichloroacetic acid. Zero time controls were obtained by adding all the reagents directly to a solution of trichloroacetic acid.

**RESULTS**

Table I shows the enzyme requirements for accumulation of PE in a system in which ATP is generated by the glycolytic reactions leading from fructose-DP to phosphoglycerate. Pyruvate is phosphorylated by reversal of the pyruvate kinase reaction. It will be noted that PE accumulation is strongly dependent on the presence of lactate dehydrogenase; reoxidation of DPNH formed in the glyceraldehyde-3-P dehydrogenase reaction is necessary to maintain a high level of 1,3-diphosphoglycerate which in turn, via the phosphoglycerate kinase reaction, permits a high ATP:ADP ratio required for reversal of the pyruvate kinase reaction.

Table II records an experiment designed to show that the amount of PE present depends on the establishment of equilibrium mixtures of the various components through the linked

* For DPN reduction, 0.02 ml. of 95 per cent ethyl alcohol and 500 μg. of alcohol dehydrogenase were added.
† Dihydroxyacetone phosphate.
In incubation at 30°. The incubation mixtures contained, in
6.0 ml.: 400 μmoles of tris(hydroxymethyl)amino methane*; 4
μmoles of MgCl₂; 516 μmoles of potassium pyruvate; 30 μmoles of
ATP; 200 μg. of pyruvate kinase. At 20 minutes and at 30 minutes,
2.2 ml. were removed from each incubation mixture and
added to 0.22 ml. of 50 per cent trichloroacetic acid. Concentra-
tions below are given as μmoles per ml.

The pH of tris(hydroxymethyl)amino methane buffer was
varied to give the final H⁺ concentrations shown in the table.

Pyruvate concentration is calculated as the initial concen-
tration (86 μmoles per ml.) minus the PE concentration.

Therefore,

\[ \frac{\text{MgATP}^2\text{−}}{\text{Mg}^{++}(\text{ATP}^\text{−})} = 3000 \] (2)

\[ \frac{\text{MgADP}^\text{−}}{\text{Mg}^{++}(\text{ADP}^\text{−})} = 1000 \] (3)

Under the conditions of the experiment, where the concentra-
tion of ATP greatly exceeded that of MgCl₂, substantially all
of the magnesium in the system, 0.67 μmoles per ml., was in the
form of nucleotide complexes (20). Binding of magnesium by
PE is insignificant compared with binding by ATP and ADP
(21, 22).

Also,

\[ \text{ADP}^\text{−} = \text{ADP}^\text{−} - \text{MgADP}^\text{−} \] (6)

\[ \text{ATP}^\text{−} = \text{ATP}^\text{−} - \text{MgATP}^\text{−} \] (7)

Substitution of Equation 5 into Equation 7 gives

\[ \text{ATP}^\text{−} = \text{ATP}^\text{−} - 0.67 + \text{MgADP}^\text{−} \] (8)

Substitution of Equations 5, 6, and 8 into Equation 4 gives

\[ \frac{(0.67 - \text{MgADP}^\text{−})(\text{ADP}^\text{−} - \text{MgADP}^\text{−})}{(\text{MgATP}^\text{−})(\text{ATP}^\text{−} - 0.67 + \text{MgADP}^\text{−})} = 3 \] (9)

MgADP^− can be computed from Equation 9 by use of the
experimentally found values for ADP^− and ATP^−. From Equa-
tions 5, 6, and 7, MgATP^−, ATP^−, and ADP^− can be computed.

Assuming that the magnesium complexes of the nucleotides

The other constituents of the mixtures; they are very reproducible
and are in excellent agreement with PE determinations made by
measuring DPNH oxidation in the coupled pyruvate kinase
and lactic dehydrogenase reactions. The pyruvate kinase used
in this study was free of myokinase and enolase. In view of these
considerations, calculations of the equilibrium constant based
on the PE determinations are presented in Table VI. Pyruvate
concentration is taken as initial pyruvate minus PE; ATP as
initial ATP minus PE; ADP as equal to PE. K equals 1.15 ×
10^8.

At first sight the constancy of the equilibrium constant calcu-
lated without regard to pH effects on ionic species and to magne-
sium complexes may be surprising. However in the pH range
covered in this study (7.72 to 8.70) ATP, ADP, and PE are in
their completely dissociated forms since the respective relevant
pK’s of these compounds are 6.6, 6.6, and 6.4 (18). As to the
effect of magnesium complexes, the following calculations show
that, under the experimental conditions, they would produce
relatively small changes in the equilibrium mixtures. From
the data of Smith and Alberty (19),

\[ \frac{(\text{MgATP}^2\text{−})}{(\text{ADP}^\text{−}){\text{(ATP}^\text{−}) = 3000 \] (2)

\[ \frac{(\text{MgADP}^\text{−})}{\text{(ATP}^\text{−})} = 1000 \] (3)

Therefore,

\[ \frac{(\text{MgATP}^2\text{−})}{(\text{ADP}^\text{−}){\text{(ATP}^\text{−})} = 3 \] (4)

are not substrates for pyruvate kinase (see Table VII), the equation for the equilibrium constant is

$$\frac{\text{ATP}^- \text{pyruvate}^-}{\text{ADP}^- \text{PE}^+ \text{H}^+} = K$$

(10)

Table VIII lists the values for ADP$^-$ and ATP$^-$ and the equilibrium constants calculated on this basis. The magnitude of $K$ is about 10 per cent less than it is when calculated, as in Table V, on the basis of total ATP and ADP. This follows from the fact that proportionately more ATP than ADP has formed a complex with Mg$^{2+}$.

**DISCUSSION**

At present it is not known whether reversal of the pyruvate kinase reaction is quantitatively significant in the synthesis of fructose-DP from pyruvate in vivo. The two glycolytic reactions of this series most unfavorable for reversal are those catalyzed by phosphoglycerate kinase ($K = 3 \times 10^3$ (12)) and by pyruvate kinase ($K = 2 \times 10^6$ (17) presumably at pH 7.6 (21)). However, the former reaction is often described as "readily reversible" and is generally regarded as obligatory in schemes of hexose formation from pyruvate, whereas the latter is considered to be incapable of significant reversal (2-5). The demonstrated reversibility of both reactions does not justify such a distinction between them. Reversal of glycolysis in vivo by direct phosphorylation of pyruvate is therefore a strong possibility.

Kalckar (23) observed that oxidation of malate by kidney extracts gave rise to PE. He proposed, in view of the apparent irreversibility of the pyruvate kinase reaction (24), that the system studied by him might be involved in providing PE for hexose synthesis. Bartley (25) with the use of kidney particles, obtained PE synthesis during the oxidation of various citric acid cycle intermediates and also when pyruvate was the substrate; PE was formed from pyruvate only in the presence of bicarbonate. Conversion of pyruvate to PE was therefore considered to involve a preliminary carboxylation to a C$_3$ compound. These findings together with isotope distribution in liver glycogen after administration of C$^4$-labeled pyruvate or C$^4$O$_2$ (cf. review by Weinman et al. (5)) support the possibility that pyruvate incorporation into glycogen proceeds by condensation of pyruvate with CO$_2$, formation of a symmetrical dicarboxylic acid, and subsequent phosphoryl decarboxylation (26, 27).

These data do not rule out glycogen synthesis by way of the pyruvate kinase reaction. Randomization of the isotopic C of pyruvate can be as readily explained by "shuttling" as by a predominantly "one-way" reaction; net synthesis of glycogen may still depend upon the pyruvate kinase reaction (28).
