SUMMARY

The action of prostaglandins on cyclic AMP levels in rat epididymal fat pads, isolated fat cells, and other tissues was studied.

Fat pads incubated with prostaglandin E₁ (PGE₁) contained higher levels of cyclic AMP than controls but lipolysis was not stimulated. However, PGE₁ did not cause increased cyclic AMP levels in isolated fat cells, suggesting that the stimulatory action occurred in another cell type. PGE₁ at very low concentrations antagonized the action of epinephrine on cyclic AMP levels in both intact fat pads and isolated fat cells.

PGE₁ was considerably more effective as an inhibitor of epinephrine than PGF₁α and PGF₂α was without effect. PGE₁ lowered cyclic AMP levels in isolated fat cells very rapidly, and was effective against adrenocorticotropic hormone, glucagon, and thyroid-stimulating hormone as well as the catecholamines.

Incubation of intact cell preparations of lung, spleen, diaphragm, kidney, and other tissues with 2.8 μM PGE₁ resulted in increased levels of cyclic AMP.

Studies by Bergström and others have established the prostaglandins as compounds of great biological importance. The actions, occurrence, metabolism, and biosynthesis of the prostaglandins have been the subject of a recent symposium (1) and two reviews (2, 3), to which the interested reader is referred.

Effects of prostaglandins on the rat epididymal fat and the toad bladder suggested that cyclic AMP might be involved at least in part in their actions. First, Steinberg and Vaughan, working in association with Bergström, found the prostaglandin E₁ antagonized the lipolytic actions of the catecholamines, adrenocorticotropic hormone, glucagon, and thyroid-stimulating hormone (4), and that the activation of phosphorylase by these hormones was also inhibited by PGE₁. Since cyclic AMP had been implicated in the hormonal activations of lipolysis (5) and phosphorylase (6), it was conceivable that the prostaglandins acted in adipose tissue by altering cyclic AMP levels. Another action of PGE₁ which seemed to involve cyclic AMP was reported by Orloff, Handler, and Bergström (7), who showed that the effects of vasopressin on water and ion movement in the toad bladder were antagonized by PGE₁. Cyclic AMP, which mimics the action of vasopressin on the toad bladder and which mediates the effect of the hormone (8), was not antagonized by PGE₁.

In the experiments being reported, low concentrations of prostaglandins decreased intracellular cyclic AMP levels in isolated fat cells very rapidly and with considerable specificity. By contrast, incubation with PGE₁ increased cyclic AMP levels in other tissues, including a component of whole fat pads, lung, spleen, diaphragm, and other tissues. A preliminary report of some of this work has been published (9).

EXPERIMENTAL PROCEDURE

In the experiments involving the incubation of intact fat pads, the pads were removed from young male rats under Nembutal anesthesia. They were divided into proximal, medial, and distal segments, and then distributed on this basis into 50-ml flasks containing 20 ml of Krebs-Ringer phosphate buffer with 200 μg per ml of albumin. The flasks were incubated for 24 min at 37°C, and then the tissues were transferred to fresh Krebs-Ringer phosphate buffer containing the desired additions. These flasks were incubated for an additional 24 min with shaking, and the experiment was terminated by removing the pieces of fat from the flasks and dropping them into an operating Waring Blendor containing 20 ml of Krebs-Ringer phosphate buffer with 200 μg per ml of albumin. The flasks were incubated for 24 min at 37°C, and then the tissues were transferred to fresh Krebs-Ringer phosphate buffer containing the desired additions. These flasks were incubated for an additional 24 min with shaking, and the experiment was terminated by removing the pieces of fat from the flasks and dropping them into an operating Waring Blendor containing 17 ml of 0.1 N HCl containing purified tritiated cyclic AMP (about 10,000 dpm). The homogenates were placed in a boiling water bath for 15 min and centrifuged at 8000 × g for 15 min, and the supernatant fractions were fractionated and cyclic AMP was analyzed as described in the accompanying report (10).

Isolated fat cells were prepared as described in the accompanying publication (10). Crystalline prostaglandins were obtained

1 The abbreviations used are: PGE₁ (prostaglandin E₁), 11α,15-(S)-dihydroxy-9-oxo-13-trans-prostenioic acid; PGF₁α (prostaglandin F₁α), 9α,11α,15-(S)-trihydroxy-13-trans-prostenioic acid; PGF₂α (prostaglandin F₂α), 9α,11α,15-(S)-trihydroxy-13-trans-prostenioic acid.
Effects of Prostaglandins on Cyclic AMP Levels

Vol. 243, No. 8

Effects of Prostaglandins on Cyclic AMP Levels

Fig. 1. The effect of PGF on cyclic AMP levels in the rat epididymal fat pad in vitro. Fat pads were removed from young male rats under pentobarbital anesthesia. The pads were divided into proximal, medial, and distal segments, and then distributed on this basis into 50-ml flasks containing 20 ml of Krebs-Ringer phosphate buffer. The flasks were incubated for 24 min at 37°C, and then the pads were transferred to fresh Krebs-Ringer phosphate buffer containing the additions as shown. PGF was prepared for use as described under "Experimental Procedure," and the dilution of the PGF was made in the control solution. These flasks were incubated for an additional 24 min with shaking, and the experiment was terminated by removing the pieces of fat pad from the flasks and dropping them into an operating Waring Blender containing 17 ml of 0.1 M HCl containing tritiated cyclic AMP and boiled for 12 min. After centrifugation at 8000 × g for 15 min at 4°C the supernatant fractions were filtered through glass wool and the filtrates were fractionated and analyzed as described under "Experimental Procedure." The vertical bars are the standard errors of the mean. Epi, epinephrine.

Fig. 2. The effect of PGF on cyclic AMP levels in isolated fat cells. The experimental conditions were as described under "Experimental Procedure." The lines at the top of each block are the standard errors of the mean, and the numbers in parentheses at the bottom of the figure are the number of experimental points in each group. Epi, epinephrine.

through the kindness of Dr. John E. Pike of the Upjohn Company (Kalamazoo, Michigan). They were prepared for use by dissolving an appropriate amount of prostaglandin (usually 1 mg) in 0.9 ml of 95% ethanol, adding an amount of K2CO3 equivalent to the weight of the prostaglandin, and diluting to the desired volume with buffer. These concentrated prostaglandin solutions were apparently stable when stored at -70°C. Routinely, the concentrated solutions were made up immediately before use and were kept at 0-4°C until added to the incubation vessel. All vessels not containing prostaglandins received a control solution consisting of the same amounts of ethanol, K2CO3, and buffer as in the prostaglandin solution. When prostaglandins were tested at different concentrations, the dilutions were made in the control solution.

Results

Effects of PGF on Cyclic AMP Levels in Rat Epididymal Fat Pad in Vitro—Cyclic AMP levels in fat pads incubated with 1 mM caffeine were 390 pmoles per g, and were increased about 8-fold by the addition of 5.5 μM epinephrine (Fig. 1). The addition of 0.56 or 2.8 μM PGF to fat pads incubated with epinephrine and caffeine reduced cyclic AMP levels to 900 and 1380 pmoles, respectively. Thus PGF was a potent antagonist of the actions of epinephrine on cyclic AMP accumulation. However, cyclic AMP levels were increased in fat pads incubated with 1 mM caffeine and PGF, and this change in cyclic AMP levels was large enough to have maximally activated lipolysis (5), although Steinberg et al. (4) reported that PGF was without lipolytic activity. When intracellular cyclic AMP levels and glycerol release were compared in fat pads exposed to PGF or epinephrine, an apparent dissociation between cyclic AMP levels and lipolysis occurred (Table I). Although both parameters were stimulated by epinephrine, PGF (which affected cyclic AMP more strongly than the catecholamine) was without effect on glycerol release.

Effect of PGF on Cyclic AMP Levels in Isolated Fat Cells—One of several possible explanations for these apparently paradoxical

effects of PGE₁ on whole fat pads was that the prostaglandin was antagonizing the action of epinephrine on the fat cell and stimulating accumulation of cyclic AMP in another type of cell found in the fat pad. Therefore, experiments with isolated fat cells were carried out (Fig. 2). While the addition of 5.5 μM epinephrine caused a large increase in the levels of cyclic AMP, 2.8 μM PGE₁ was without stimulatory activity. Although this concentration of PGE₁ did not increase cyclic AMP levels, the response of the fat cells to epinephrine was almost completely antagonized. This suggested that PGE₁ was stimulating cyclic AMP accumulation in a cell type other than the fat cell. However, it was also possible that the stimulatory effect of PGE₁ was on the fat cell, and that the ability of the cell to respond to PGE₁ with increased cyclic AMP levels had been destroyed by the collagenase treatment used in the preparation of the isolated fat cells. Therefore, experiments designed to clarify this point were undertaken (Fig. 3). Fat pads were incubated at 37° for about 1 hour with or without collagenase. When the fat pads incubated with collagenase were disintegrated, half of the collagenase-treated samples were filtered through a fiber glass screen and centrifuged, and the fat cells were isolated. The other collagenase-treated samples and the fat pads incubated without collagenase were diluted but not filtered or centrifuged. Caffeine, PGE₁, and epinephrine were then added to the samples as indicated and incubated for 10 min, and cyclic AMP levels were measured. PGE₁ did not stimulate the isolated fat cells, although cyclic AMP levels increased 3-fold in the whole fat pad and in the samples treated with collagenase but not separated. Epinephrine was stimulatory in all three preparations and PGE₁ antagonized the effects of epinephrine.

Comparison of Activity of PGE₁ with Other Prostaglandins—The cyclic AMP response of isolated fat cells incubated with 1 mM caffeine and 5.5 μM epinephrine was sensitive to low concentrations of PGE₁ (Fig. 4). The action of epinephrine was inhibited 50% by approximately 0.004 μM PGE₁, and small but significant effects of PGE₁ were detectable at 0.00004 μM, which was the lowest concentration tested. PGE₂ was much less effective than PGE₁, and PGE₃ was without effect on the cyclic AMP response of isolated fat cells.

Time Course of Action of PGE₁—PGE₁ lowered intracellular cyclic AMP levels in isolated fat cells very rapidly (Fig. 5). Isolated fat cells were incubated with 1 mM caffeine and 5.5 μM epinephrine for 10 min and then incubated with PGE₁ for 1, 2, 4, or 8 min. During the 1st min of incubation with PGE₁, cyclic AMP levels were not significantly changed, but from Minute 1 to Minute 2 the levels were sharply decreased. A rapid rate of decline in the level of cyclic AMP was maintained between Minutes 2 and 4, and although it slowed, by Minute 8 cyclic AMP was near the control level.

Effect of PGE₁ on Cyclic AMP Levels in Isolated Fat Cells Exposed to Epinephrine, Adrenocorticotropic Hormone, Glucagon,
or Thyroid-stimulating Hormone in Presence of 1 mM Caffeine—PGE1 effectively lowered increased levels of cyclic AMP engendered by adrenocorticotropic hormone, glucagon, and thyroid-stimulating hormone as well as epinephrine (Fig. 6). PGE1 was at least as effective against adrenocorticotropic hormone, glucagon, and thyroid-stimulating hormone (p < 0.01) as it was against epinephrine.

Effects of PGE1 on Other Tissues—Incubation of rat lung pieces with 2.8 μM PGE1 in the presence of 1 mM caffeine caused increased levels of cyclic AMP (Table II). PGE1 did not cause any obvious lowering of cyclic AMP levels when added to lung pieces incubated with epinephrine and caffeine. Cyclic AMP levels were increased in rat kidney slices and in minced rat testes. PGE1 also stimulated cyclic AMP accumulation in rat kidney slices and in minced rat testes.

**DISCUSSION**

That cyclic AMP is involved in the antilipolytic action of the prostaglandins on fat cells seems very probable. The role of cyclic AMP in the actions of lipolytic hormones and the methyl xanthines appears to be well established (5), and the
Prostaglandins decreased cyclic AMP levels qualitatively, quantitatively, and temporally as they antagonized lipolysis.

However, there are other aspects of the relationships between prostaglandins and cyclic AMP which are much less clear. First is the question of how PGE₁, for example, decreases cyclic AMP levels in isolated fat cells. Actions of PGE₁ have not been elicited in broken cell preparations of isolated fat cells. The turnover of cyclic AMP in intact cells is high (e.g. see Fig. 5) and it is difficult if not impossible to obtain an unequivocal answer about the site of PGE₁ action (i.e. inhibition of adenyl cyclase or stimulation of the phosphodiesterase) in such preparations. Steinberg and Vaughan reported that PGE₁ did not antagonize the lipolytic actions of exogenous cyclic AMP or N⁶-2'-O-dibutyryl cyclic AMP (11, 12). This indicated that PGE₁ acted to inhibit adenyl cyclase in adipose tissue, as had been suggested earlier by Orloff, Handler, and Bergström (7) working with toad bladder. On the other hand, Mühlbacherova, Solyom, and Pugliš (13) have suggested on the basis of lipolytic measurements that prostaglandins stimulate the phosphodiesterase. Such experiments, however, are rather indirect and a final judgment must await the demonstration of an action of PGE₁ on one or another of these enzymes. Also, it is possible that the effects of PGE₁ on cyclic AMP levels in fat cells may be secondary to another action, e.g. a configurational change in the plasma membrane, or perhaps actions on some as yet undefined second messenger which produces the effect on adenyl cyclase or phosphodiesterase.

Second, the mechanisms by which PGE₁ both stimulates cyclic AMP accumulation by itself and antagonizes lipolytic hormones in the whole fat pad are not wholly understood. Since this stimulatory action is lost when fat cells are separated from the rest of the fat pad it seems that another cell type is involved. Unfortunately, this cell type has not been identified. This dualistic action of PGE₁ on the fat pad emphasizes the fact that certain tissues, including fat, release increased amounts of prostaglandins to the medium when stimulated by hormones (15). This suggests that in some way the release of prostaglandins and the activation of the cyclic AMP mechanism (e.g. adenyl cyclase) may be related. However, it is also quite possible that the release of prostaglandins may be due to an action of increased cyclic AMP, and that prostaglandins may then serve as a feedback mechanism, modulating adenyl cyclase, as has been suggested by Bergström (3).

Acknowledgments—We would like to thank Dr. Earl W. Sutherland for his continued interest in this work. Dr. John E. Piké of The Upjohn Company, Kalamazoo, Michigan, has provided several helpful discussions and the prostaglandins used in these studies, for which we are very grateful. In addition, we would like to acknowledge the valuable technical assistance of Alta Jackson, Nina Wendt, Joseph Campbell, and Ted D. Chrisman.
