Protein disulfide isomerase associated 3 (Pdia3) is a multifunctional protein hypothesized to be a membrane receptor for 1,25$(OH)$. In intestinal epithelium and chondrocytes, 1,25$(OH)$. stimulates rapid membrane responses that are different from genomic effects via the vitamin D receptor (VDR). In this study, we show that 1,25$(OH)$. stimulates phospholipase A$_2$ (PLA$_2$)–dependent rapid release of prostaglandin E$_2$ (PGE$_2$), activation of protein kinase C (PKC), and regulation of bone related gene transcription and mineralization in osteoblast-like MC3T3-E1 cells (WT) via a mechanism involving Pdia3. Pdia3 was present in caveolae based on co-localization with lipid rafts and caveolin-1. In Pdia3-silenced (Sh-Pdia3) cells, 1,25$(OH)$. failed to stimulate PKC and PGE$_2$ responses; in Pdia3-overexpressing cells (Ov-Pdia3), responses to 1,25$(OH)$. were augmented. Downstream mediators of Pdia3, PLA$_2$ activating protein (PLAA) and arachidonic acid, stimulated similar PKC activation in wild type, Sh-Pdia3 and Ov-Pdia3 cells supporting the hypothesis that Pdia3 mediates the membrane action of 1,25$(OH)$. Treatment of MC3T3-E1 cells with 1,25$(OH)$. for 9 minutes stimulated rapid phosphorylation of extracellular signal–regulated kinase 1 and 2 (ERK1/2) and increased expression of alkaline phosphatase, MMP-13, and osteopontin but decreased expression of osteocalcin, osteoprotegerin (mRNA and protein) and smad2. These effects were attenuated in Sh-Pdia3 cells. Sh-Pdia3 cells produced higher numbers of von Kossa-positive nodules and alizarin red-positive nodules compared to WT cells with or without 1,25$(OH)$. treatment while Ov-Pdia3 did not show any mineralization. Our data suggest Pdia3 is an important initiator of 1,25$(OH)$. stimulated membrane signaling pathways, which have both genomic and non genomic effects during osteoblast maturation.

The secosteroid 1,25-dihydroxy vitamin D$_3$ [$1\alpha$,$25$(OH)$_2$D$_3$] regulates osteoblasts through both the classic vitamin D receptor (VDR) mediated genomic pathway and through membrane receptor mediated rapid responses (1-3). In osteoblasts, the VDR acts by binding with vitamin D response elements (VDRE) to modulate gene transcription (4,5). Rapid membrane signaling has been shown to regulate calcium, phosphate and chloride transport though ion channels (6-8). The VDR has been implicated in these rapid responses to 1$\alpha$,$25$(OH)$_2$D$_3$ (9,10). However, studies using analogues to the secosteroid with low VDR binding affinities indicate that the structural features of 1$\alpha$,$25$(OH)$_2$D$_3$ are important in stimulating the membrane response, suggesting the existence of a specific membrane receptor (8).

Protein disulfide isomerase associated 3 (Pdia3, also known as ERp60, ERp57, Grp58, and 1,25-MARRS) has been identified as a potential candidate as an alternate membrane-associated receptor for 1$\alpha$,$25$(OH)$_2$D$_3$ (11). It has been intensively studied as a chaperone protein in glycoprotein folding (12) and major histocompatibility complex I loading (13). Unlike other protein disulfide isomerase family members, Pdia3 exists not only in the endoplasmic reticulum but also in the nucleus, extracellular matrix, and plasma membrane, suggesting additional functions (3). Pdia3 purified from chick intestinal epithelium (14) exhibits saturable binding to 1$\alpha$,$25$(OH)$_2$D$_3$. More recently, antibody-blocking and ribosome-knock down experiments have further linked this protein to rapid responses to 1$\alpha$,$25$(OH)$_2$D$_3$ both in rat chondrocytes and chick intestinal epithelial cells (11,15). Taken together, these observations support a role for Pdia3 as a membrane receptor.
for the secosteroid.

Multiple cell models have been used to elucidate the role of membrane signaling by 1α,25(OH)2D3. In growth plate chondrocytes, 1α,25(OH)2D3 regulates phospholipase A2 (PLA2), phospholipase C (PLC), intracellular Ca++ and protein kinase C (PKC) (16-18). In osteoblasts, 1α,25(OH)2D3 has also been shown to activate PLC and PKC as well as regulating voltage gated ion channels and increasing PLA2 activity and prostaglandin production (PGE1 and PGE2) (10,19-21). These data suggest that the rapid membrane signaling pathway discovered in chondrocytes may also function in osteoblasts.

One function of membrane signaling is to regulate gene transcription. 1α,25(OH)2D3 modulates gene transcription. One function of membrane signaling is to initiate this rapid signaling. Third, we showed Pdia3 is required for the secosteroid.

Experimental Procedures

Pdia3 Knock Down and Overexpression - Pdia3 shRNA probes were designed to target the mouse Pdia3 mRNA (NM_007952). Five different sequences were generated and incorporated into lentivirus particles (SHCLNV-NM 007592, Sigma-Aldrich, St. Louis, MO). To select the optimal shRNA, mouse MC3T3-E1 osteoblasts (CRL-2593, ATCC, Manassas, VA) were plated at a density of 20,000 cells/cm2 in a 24-well plate in α-MEM supplemented with 10% FBS, 1% P/S and 8µg/mL hexadimethrine bromide and transduced with lentivirus particles at multiplicity of infection (MOI) of 7.5. Cells containing shRNAs or empty vectors were selected by culturing the cells for two weeks in media containing 2.0 µg/ml puromycin. Loss of Pdia3 expression was quantified by real-time PCR and verified by western blot using anti-Pdia3 antibody (Alpha Diagnostic International Inc., San Antonio, Texas). A stable transduced cell line with 80% knockdown of Pdia3 was chosen. The shRNA targeted the 3’UTR region of Pdia3 mRNA (ggaccagttatgtttgtggttt, #N0000011436, Sigma-Aldrich).

To overexpress Pdia3, MC3T3-E1 cells were plated at a density of 20,000 cells/cm2 in a 24 well plate in α-MEM supplied with 10%FBS. After 24 hours, 100µl of Opti-MEM (Invitrogen, Carlsbad, CA) containing 2.0µl lipofectamine 2000 (Invitrogen) and 0.8µg pCMV6-Kan/Neo empty vector (OriGene, Rockville, MD) or overexpression plasmid (#MC200134, OriGene) that contained full length of mouse Pdia3 cDNA (BC003285.1) was added into each well. After 48 hours, cells were selected in media containing 550 µg/mL G418 for two weeks. mRNA and protein were quantified by real-time PCR and western blot as described above. A stable transfected cell line with 100% overexpression of Pdia3 was chosen.

Cell Culture- Wild type MC3T3-E1 cells, MC3T3-E1 cells silenced for Pdia3 (Sh-Pdia3), and MC3T3-E1 cells overexpressing Pdia3 (Ov-Pdia3) were plated in T75 flasks (10,000 cells/cm2) and cultured in α-MEM containing 10% FBS and 1% P/S. Puromycin (2µg/ml) was included in the media of Sh-Pdia3 cells and G418 (550µg/ml) was included in the media of Ov-Pdia3 cells. At confluence, cells were subcultured at the same plating density. 48 hours after plating the media were replaced with α-MEM supplemented with 5%FBS, 1% P/S and 1% vitamin C. After 12 days in culture, the cells were treated with media containing either the 1α,25(OH)2D3 vehicle (ethanol) alone or with the appropriate dose of 1α,25(OH)2D3.

Plasma Membranes and Caveolae- A detergent-free method of plasma membrane and caveolae isolation was used as described previously (25). MC3T3-E1 cells were cultured for 12 days and harvested by scraping in isolation buffer (0.25M sucrose, 1mM EDTA, 20mM tricine, PH=7.8).
Samples were homogenized using a tissue grinder for twenty strokes. Homogenates were centrifuged at 20,000g for 10mins to pellet cell debris, including nucleus, mitochondria, and endoplasmic reticulum. The supernatant was collected, placed on top of 30% Percoll (GE Healthcare, Piscataway, NJ) in isolation buffer, and then centrifuged for 30 mins at 84,000g. The plasma membranes formed a visible band and were collected by aspiration. Plasma membranes were layered on a 10%-20% OptiPrep gradient (Sigma-Aldrich) and centrifuged at 52,000g for 90mins. The top layer was collected, overlaid with 5% OptiPrep, and centrifuged at 52,000g for another 90mins. Fractions were collected from the top to the bottom in thirteen fractions. The caveolae existed as an opaque band, which was collected in Fraction 3, based on the presence of caveolin-1 as described below.

**Western Blot**- Gel electrophoresis was performed using NuSep 4-20% LongLife Gels (NuSep, Lawrenceville, GA). Proteins were transferred from gels to nitrocellulose membrane using an iBlot Dry Blotting System (Invitrogen). The membrane was subsequently blotted in 1% bovine serum albumin (BSA) in phosphate buffered saline (PBS) for one hour. Next, samples were incubated overnight with antibodies against Pdia3 (Alpha Diagnostic International); caveolin-1 (sc-894, Santa Cruz Biotechnology, Santa Cruz, CA); or glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (MAB374, Millipore, Billerica, MA). After washing three times with PBS containing 0.05% Tween-20, the membrane was incubated with goat anti-rabbit or goat anti-mouse horse radish peroxidase conjugated secondary antibodies (Bio-Rad, Hercules, CA) in PBS containing 5% dry milk and 0.05% Tween-20 for one hour. After three washes, the membrane was developed using SuperSignal West Pico Chemiluminescent System (Thermo Fisher Scientific, Rockford, IL) and imaged with VersaDoc imaging system (Bio-Rad, Hercules, CA).

**Immunofluorescence**- Immunofluorescence was used to assess Pdia3 protein in intact cells. Wild type, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1 cells were plated at 10,000 cells/cm² on a glass chamber slide for 24 hours. The cells were fixed in 4% paraformaldehyde for 20mins and permeabilized with 0.01% Triton-X 100 for 10mins. Cells were then incubated with 1:100 dilution of Hoechst 33342 (Invitrogen), Pdia3 primary antibody, and 1:40 dilution of Alexa Fluor 555 phallloidin (Invitrogen) in a PBS containing 1%BSA. After washing, cells were incubated with goat anti-rabbit Alexa 488 (Invitrogen) in 1%BSA-PBS.

In order to determine if Pdia3 was associated with a specific plasma membrane compartment, co-localization experiments were performed. Cells in suspension were labelled with Vybrant Lipid Rafts Labeling Kits-Alexa Fluor 594 (Invitrogen). After labeling, cells were fixed in 4% paraformaldehyde for 20mins. Then, cells were further stained with Pdia3 primary antibody and 1:100 (v/v) Hoechst 33342 in 1%BSA-PBS. After washing, cells were incubated with goat anti-rabbit Alexa 488 in 1%BSA-PBS, fixed with GEL/MOUNT (Biomeda Corp, Foster City, CA), and imaged using a Zeiss LSM 510 confocal microscope.

**Signaling by 1α,25(OH)2D3**- To study the effect of 1α,25(OH)2D3 on PKC activity, cells were treated with vehicle (ethanol) or 10⁻¹⁰, 10⁻⁹ or 10⁻⁸M 1α,25(OH)2D3 for 9mins, based on the observation that 1α,25(OH)2D3 activates PKC in chondrocytes at this time point (26). The effect of 1α,25(OH)2D3 on PKC is via a PLA₂-dependent pathway (16). To determine if this is also the case for MC3T3-E1 cells, one half of the cultures were treated with 10⁻⁵M of the PLA₂ inhibitor quinacrine (Calbiochem, San Diego, CA). Quinacrine was added to media 30mins before and maintained during 1α,25(OH)2D3 treatment. Cells were also treated for 9min with 0, 10⁻⁸, 10⁻⁷, 10⁻⁶M PLA₂ activating protein (PLAA) (Enzo Life Sciences International, Inc, Plymouth Meeting, PA) as well as with 0, 10⁻⁶, 10⁻⁵, or 10⁻⁴M arachidonic acid (AA) (Calbiochem), which is the product of PLA₂ action. Media were collected and cell layers were washed twice with PBS and lysed in 300μl RIPA buffer (20mM Tris-HCl, 150mM NaCl, 5mM disodium EDTA, 1%NP-40). PKC activity was measured using a commercial kit (RPN77, GE Healthcare) and normalized by total protein. To measure rapid PGE₂ release into the media, cells were treated with vehicle (ethanol), 10⁻¹⁰, 10⁻⁹, or 10⁻⁸M 1α,25(OH)2D3. After 30min treatment, the media were acidified and PGE₂ was measured using a commercial kit (Perkin Elmer, Waltham, MA) and normalized by cell number.
ERK1/2- To determine if the rapid responses to 1α,25(OH)2D3 result in ERK1/2 activation, phosphorylation of ERK1/2 was determined using an ELISA assay. After 12 day’s culture, cells were treated for 9 mins with media containing vehicle (ethanol) or 10^-8 M 1α,25(OH)2D3. Media were replaced and cells were harvested 0, 30 and 90 mins later. Phospho-ERK1/2 was measured in cell layer lysate using a mouse Phospho-ERK1/2 ELISA kit (R&D system, Minneapolis, MN).

Gene Expression- After 12 day’s culture, cells were treated with media containing vehicle (ethanol) or 10^-8 M 1α,25(OH)2D3. After 9 mins, media were replaced with fresh media for another 8 hours. RNA was extracted using TRIzol (Invitrogen) and reverse-transcribed into cDNA using the Omniscript RTkit (Qiagen, Valencia, CA) according to the manufacturer’s directions. Real-time PCR was performed using SYBR Green SuperMix 170-8882 (Bio-Rad) for osteocalcin (OCN, NM_001032298), alkaline phosphatase (ALP, NM_007431), bone sialoprotein (BSP, NM_008318), osteopontin (OPN, NM_009263), osteoprotegerin (OPG, NM_009242), Smad2 (NM_010754), inositol 1,4,5-trisphosphate 3-associated 3 (Pdia3, NM_007952), Runx2 (NM_011613), protein disulfide isomerase associated 3 (Pdia3, NM_007952), Runx2 (NM_009820), inositol 1,4,5-trisphosphate 3-kinase A (ITPKA, NM_146125), osteonectin (OTN, NM_009242), Smad2 (NM_010754), Vitamin D receptor (VDR, NM_009504), and glyceraldehyde 3-phosphate dehydrogenase (GAPDH, NM_008084). Oligonucleotide primers were designed using Beacon Designer 7.0 software (Supplemental Table 1). A homology blast search was performed within the mammalian genome to exclude the possibility of sequence similarity. Real-time PCR was performed using an iCycler PCR machine (Bio-Rad) with iCycler software. Data were normalized to the endogenous reference gene GAPDH.

Osteopontin- Changes in osteopontin secreted into the conditioned media were used as an outcome measure of the rapid signaling pathway. The role of Ca++ ions was examined by incubating the cells with 10^-4 M Ca++ chelator BAPTA-AM (Sigma-Aldrich). The role of PLA2 was assessed by treating the cells with 10^-5 M quinacrine. For these experiments, cultures were treated with media containing the inhibitor vehicle (ddH2O) or inhibitor for 30 mins. Fresh media containing the 1.25(OH)2D3 vehicle (ethanol) or the inhibitor plus 10^-8 M 1α,25(OH)2D3 were added. Nine mins later, the media were replaced by fresh media and these media were collected 24 hours later. Osteopontin in the conditioned media was determined by ELISA using a mouse osteopontin ELISA kit (R&D Systems).

Calcification- To determine if Pdia3 modulates terminal osteoblast differentiation, we assayed the ability of the cells to mineralize their extracellular matrix. Cells were plated in 24-well plates in full media and cultured as described above. At confluence, full media were changed for osteogenic media (α-MEM supplemented with 5% FBS, 1% P/S, 100µg/ml ascorbic acid, 10mM β-glycerol phosphate and 10^-7 M dexamethasone) or growth media (α-MEM supplemented with 5% FBS, 1% P/S). Every 48 hours, the osteogenic media were replaced with growth media containing vehicle (ethanol) or 10^-8 M 1α,25(OH)2D3 for 9 mins; these media were then removed and replaced with osteogenic media. Growth media were replaced every two days without additional 1α,25(OH)2D3. On day 28 after plating, media were replaced with osteogenic media containing 10% alamar blue for 40 minutes to assess viability of the cells. In healthy cells, alamar blue is reduced by components of the electron transport chain, resulting in red fluorescence. The cultures were then fixed in 10% formalin and alizarin red and von Kossa staining were performed.

Statistical Analysis- For each experiment, each data point represents the means ± SEM for six individual cultures. Each experiment was repeated two or more times to ensure the validity of the data. The data presented are from a single representative experiment. Significance was determined by analysis of variance and post hoc testing performed using Bonferroni’s modification of Student’s t test for multiple comparisons. p ≤0.05 was considered to be significant.

RESULTS

Rapid Membrane Response in MC3T3-E1 Cells. PKC activity in MC3T3-E1 cells was stimulated by 1α,25(OH)2D3 in a dose dependent-manner (Fig.1a). This effect was rapid, occurring within 9 mins of treatment. 1α,25(OH)2D3 also caused a dose-dependent increase in PGE2 content of the
conditioned media at 30 mins (Fig.1b), suggesting that PLA\(_2\) had been activated. Inhibition of PLA\(_2\) with quinacrine blocked the stimulating effect of 1\(\alpha\),25(OH)\(_2\)D\(_3\) on PKC at all concentration treated. Moreover, the PLA\(_2\) activator, PLAA, and the product of PLA\(_2\) action, arachidonic acid both stimulated PKC activity to a similar extent. PLAA caused a dose-dependent increase in PKC activity at 10\(^{-7}\)M to 10\(^{-5}\)M (Fig.1c); arachidonic acid increased PKC at 10\(^{-5}\)M (Fig.1d). These results indicate that 1\(\alpha\),25(OH)\(_2\)D\(_3\) regulated PKC via a mechanism that required PLA\(_2\).

**Subcellular Location of Pdia3.** Western blots of whole cell lysates and isolated plasma membranes indicated that both Pdia3 and caveolin-1 were present (Fig.2a). Pdia3 was present in fractions 1, 2, 3 and 4 of the plasma membranes whereas caveolin-1 was present only in fraction 3 (Fig.2b). These observations were supported by confocal microscopy. Both Pdia3 and lipid rafts were distributed over the surface of non-permeabilized MC3T3-E1 cells. When the immunofluorescent images were merged, part of staining overlapped. However, a small portion of fluorescently labeled Pdia3 was not associated with lipid rafts.

**Pdia3 Expression in MC3T3-E1 Cells.** Two MC3T3-E1 cell lines were established that were silenced for expression of Pdia3 or that over-expressed this protein. RT-PCR indicated that mRNA for Pdia3 was reduced in Sh-Pdia3 cells compared to wild type cells whereas expression was increased in Ov-Pdia3 cells (Fig.3a). Real-time PCR analysis of six independent cultures showed Pdia3 expression was decreased by 80% in Sh-Pdia3 cells; it increased by 200% in Ov-Pdia3 cells (Fig.3b). Western blots of whole cell lysates confirmed that Pdia3 protein was affected in a comparable manner. Pdia3 protein was reduced by 75% in the Sh-Pdia3 cells and increased by 70% in Ov-Pdia3 cells (Fig.3c). Western blots of plasma membranes showed similar results. Pdia3 protein was decreased by 80% in plasma membranes from Sh-Pdia3 cells and increased by 30% in plasma membranes from Ov-Pdia3 cells (Fig.3d). Similarly, MC3T3-E1 cells exhibited intense immunofluorescence for Pdia3 surrounding the nucleus, but this staining was largely decreased in Sh-Pdia3 cells; it was augmented in Ov-Pdia3 cells (Fig.3e).

**Role of Pdia3 in the Rapid Response to 1\(\alpha\),25(OH)\(_2\)D\(_3\).** Pdia3 mediated the rapid response of MC3T3-E1 cells to 1\(\alpha\),25(OH)\(_2\)D\(_3\). Whereas 1\(\alpha\),25(OH)\(_2\)D\(_3\) increased PKC in wild type cells, it had no effect on PKC activity in Sh-Pdia3 cells (Fig.4a). In contrast, in Ov-Pdia3 cells, 1\(\alpha\),25(OH)\(_2\)D\(_3\) increased PKC activity over the stimulatory effect of the secosteroid in wild type cells. 10\(^{-7}\)M 1\(\alpha\),25(OH)\(_2\)D\(_3\) caused a 1.8 fold increase of PKC activity in Ov-Pdia3 compared to a 1.3 fold increase in wild type cells (Fig.4a). These effects were specific to Pdia3 since the cells transfected with empty vectors responded to 1\(\alpha\),25(OH)\(_2\)D\(_3\) as the wild type MC3T3-E1 cells (Supplemental Fig.1).

Pdia3 also mediated the 1\(\alpha\),25(OH)\(_2\)D\(_3\)-dependent PLAA signaling pathway resulting in PKC activation. Production of PGE\(_2\), a downstream metabolite of PLA\(_2\) action, was increased by 1\(\alpha\),25(OH)\(_2\)D\(_3\) in MC3T3-E1 cells and this effect was enhanced in Ov-Pdia3 cells at all concentrations tested (Fig. 4b). In contrast, the stimulatory effect of 1\(\alpha\),25(OH)\(_2\)D\(_3\) was reduced in Sh-Pdia3 cells. The PLA\(_2\) pathway was functional in all three cell lines, however. Treatment of the cells with PLAA caused a dose-dependent increase in PKC that was comparable in all three cell types (Fig. 4c). Similarly arachidonic acid activated PKC to a comparable extent as 1\(\alpha\),25(OH)\(_2\)D\(_3\) in all three cell lines (Fig. 4d).

**Pdia3-Dependent Rapid Signaling Regulates Gene Expression.** Gene expression was regulated, at least in part, by Pdia3-mediated signaling (Fig. 5). Treatment of MC3T3-E1 cells with 1\(\alpha\),25(OH)\(_2\)D\(_3\) for 9mins resulted in changes in mRNA levels for bone related genes. OPN, ALP, and MMP-13 were up-regulated, while OPG, Smad2 and OCN were down-regulated. BSP, ITPKA, Runx2, OTN, VDR and Pdia3 showed no significant differences as a function of 1\(\alpha\),25(OH)\(_2\)D\(_3\) treatment. 1\(\alpha\),25(OH)\(_2\)D\(_3\) did not affect mRNA for BSP, ITPKA, Runx2, OTN VDR or Pdia3 in Sh-Pdia3 cells. However, genes that were down regulated in wild type cells (OPG, OCN and Smad2) were unaffected by 1\(\alpha\),25(OH)\(_2\)D\(_3\) in Sh-Pdia3 cells. For the three up-regulated genes (OPN, ALK and MMP-13), the effects of 1\(\alpha\),25(OH)\(_2\)D\(_3\) were reduced in the Sh-Pdia3 cells.

Pdia3 was required for 1\(\alpha\),25(OH)\(_2\)D\(_3\) dependent activation of ERK1/2. 1\(\alpha\),25(OH)\(_2\)D\(_3\) treatment caused phosphorylation of ERK1/2 by 30mins; this effect was lost by 90mins (Fig. 6a).
contrast, 1α,25(OH)₂D₃ had no effect on ERK1/2 phosphorylation in Sh-Pdia3 cells (Fig. 6b).

Changes in protein production correlated with changes in gene expression. Treatment of wild type MC3T3-E1 cells with 1α,25(OH)₂D₃ for 9mins caused a 200% increase in OPN mRNA at 8 hours (Fig. 5a) and a marked increase in OPN protein at 24 hours (Fig. 6c). This effect was attenuated in Sh-Pdia3 cells while Ov-Pdia3 cells showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase. The basal level of OPN protein was also lower in Sh-Pdia3 cells and showed an augmented increase.

**Pdia3 Regulates Mineralization.** Wild type MC3T3-E1 cells, Sh-Pdia3 cells and Ov-Pdia3 cells all formed von Kossa positive nodules. The number of alizarin-red/von Kossa positive nodules formed by wild type cells were comparable in cultures grown in growth media, osteogenic media, or osteogenic media plus 1α,25(OH)₂D₃ (Fig. 6d,e). In growth media, von Kossa positive nodule formation was reduced in Sh-Pdia3 and Ov-Pdia3 cultures compared to wild type cells although differences in Pdia3 expression did not affect the number of alizarin-red positive nodules. When Sh-Pdia3 cells were cultured in osteogenic media, the number of alizarin-red/von Kossa positive nodules was markedly increased in comparison to wild type cells. In contrast, von Kossa positive nodule formation was reduced in cultures of Ov-Pdia3 cells. Treatment with 1α,25(OH)₂D₃ blocked the stimulatory effect of the osteogenic media on von Kossa positive nodule formation in cultures of Sh-Pdia3 cells but had no effect on alizarin-red positive nodules. Moreover, treatment did not affect wild type or Ov-Pdia3 cultures. For all cell types, growth in osteogenic media resulted in decreased alamar blue staining compared to growth media (Fig. 6f). Treatment with 1α,25(OH)₂D₃ caused a further decrease only in Sh-Pdia3 cells.

**DISCUSSION**

Our data show that Pdia3 mediates effects of 1α,25(OH)₂D₃ on osteoblasts, including rapid production of PGE₂ and activation of PKC. Importantly, the results demonstrate that Pdia3 dependent signaling results in changes in gene expression, via phosphorylation of transcription factors such as ERK1/2. Taking these observations together with our previous observations using growth plate chondrocytes (16,27,28) and osteoblasts (19,21), we propose a mechanism initiated at the plasma membrane and culminating in downstream genomic regulation (Fig. 7). In this signaling pathway, 1α,25(OH)₂D₃ first binds with Pdia3 or a Pdia3-membrane receptor complex in caveolae, activating PLA₂. This results in arachidonic acid release; the arachidonic acid is processed further to PGE₂. In growth plate chondrocytes (1,16,18), PGE₂ binds its G-protein coupled receptor and activates PLC. Activated PLC acts on phosphatidylinositol, releasing inositol-trisphosphate (IP₃) and diacylglycerol (DAG). Increased intracellular Ca²⁺ due to IP₃ works with DAG to translocate and activate PKC on the plasma membrane. This pathway also results in activation of ERK1/2 (22). The fact that key components of the signaling pathway are also present in osteoblasts (19,21) and that PKC and PLC were also reported to be rapidly activated by 1α,25(OH)₂D₃ in other cell types (29-32), suggests that the proposed pathway is likely to be conserved in 1α,25(OH)₂D₃-responsive cells.

Pdia3 has been reported to be present in endoplasmic reticulum, cytosol, nucleus, plasma membranes, extracellular matrix and matrix vesicles (33). Our results show that Pdia3 is present in the cytosol and plasma membranes of MC3T3-E1 osteoblasts as well. Part of the Pdia3 is in specialized compartments of the plasma membranes, co-localizing with lipid rafts by fluorescence microscopy. Moreover, western blot shows that Pdia3 is in the caveolar fraction of the plasma membrane based on the presence of caveolin-1 (34). We previously reported caveolae are required for rapid 1α,25(OH)₂D₃-dependent PKC signaling in chondrocytes, and caveolin-1 must be present based on studies using chondrocytes from Cav-1(-/-) mice (27). This suggests that caveolae provide a microenvironment that permits the interaction of Pdia3 with 1α,25(OH)₂D₃ together with other components of the signaling complex. Pdia3 was also present in plasma membrane fractions not associated with caveolin-1 and
immunofluorescence demonstrated that not all Pdia3 was associated with lipid rafts. What role this Pdia3 may play with respect to 1α,25(OH)₂D₃, if any, is not clear.

In the present study, we were able to construct stably transfected cell lines that exhibited reduced or over expression of Pdia3. The changes in expression were confirmed by real-time PCR, confocal microscopy, and western blots. These changes in Pdia3 correlated with changes in cell response to 1α,25(OH)₂D₃, including activation of PKC, phosphorylation of ERK1/2, downstream regulation of gene expression and protein production, and ultimately, in von Kossa positive nodule formation. These results strongly implicate Pdia3 as a membrane receptor for 1α,25(OH)₂D₃. Moreover, we showed that by regulating expression of Pdia3, signaling could be either blocked or augmented. These data suggest that Pdia3 could be a determining factor, the abundance of which directly correlates with the magnitude of the membrane response.

Previous studies using antibodies to Pdia3 demonstrated a role for this protein in Ca²⁺ ion uptake in chicken intestinal epithelium (35) and as a regulator of PKC signaling (36), but they did not demonstrate in a conclusive manner that Pdia3 is upstream of the earliest steps in the signaling pathway. Here we showed that the PLA₂ pathway was intact in the Sh-Pdia3 and Ov-Pdia3 cells. If Pdia3 had been a mediator downstream of PLA₂, either PLAA, the activator of PLA₂, or arachidonic acid, the product of PLA₂ action would stimulate a different response among the three-cell lines. However, we observed a similar effect of PLAA and arachidonic acid on PKC activation in all three-cell lines, indicating that Pdia3 functions in the very first step of this signaling cascade, potentially as the membrane receptor.

It has been unclear whether the Pdia3-dependent rapid membrane response to 1α,25(OH)₂D₃ also has a genomic function. By silencing and overexpressing Pdia3, we were able to assess the potential effect of rapid signaling on gene transcription in a new perspective. In growth plate chondrocytes, the rapid translocation and activation of PKC leads to the phosphorylation of ERK1/2 (22). ERK1/2 has been shown to regulate osteoblast differentiation in multiple signaling pathways (37-39). Therefore, it is very likely for the rapid response to have a role in gene transcription through the activation of ERK1/2. In wild type cells, among the 12 bone related genes we studied, six were regulated by a 9min treatment with 1α,25(OH)₂D₃. Among the six genes, only OCN and OPN have been reported to have VDR response elements (VDRE) (40). All of the six genes have been previously reported to be regulated through a VDR-independent membrane pathway (24). Here we showed in Sh-Pdia3 cells, both rapid activation of ERK1/2 and regulation of these six genes were either completely blocked or significantly attenuated. Our result confirms the previous report and further, shows that this VDR-independent genomic effect is mediated by Pdia3.

It should be noted that three out of the six 1α,25(OH)₂D₃-regulated genes did not completely lose their response to 1α,25(OH)₂D₃ in Sh-Pdia3 cells. There are two possible explanations for this. First, in Sh-Pdia3 cells, thirty percent of Pdia3 was still on the plasma membrane to mediate the effect. Second, Pdia3 dependent rapid membrane signaling participates in these mechanisms by using kinase cascades to change activity of the transcription factor complex. Therefore, this kind of regulation may crosstalk with other pathways. For example, VDR could be phosphorylated and activated by PKC (41).

In wild type MC3T3-E1 cells, three genes were up-regulated in response to 1α,25(OH)₂D₃: ALP is an early stage osteoblast differentiation marker (42); MMP-13 is an extracellular matrix remodeling proteinase (43); and OPN has been shown to be a mineralization inhibitor (44). Three genes were down-regulated. OCN is a late stage osteoblast differentiation marker (45) and OPG inhibits osteoclast differentiation (46). This suggests that the effect of pulse treatment with 1α,25(OH)₂D₃ promotes early osteoblast differentiation and extracellular matrix remodeling but prevents late stage osteoblast differentiation and mineralization. Others have shown that OCN is increased in response to 1α,25(OH)₂D₃ via VDR-mediated transcription (47), however, our study suggests that it is regulated via Pdia3 as well, and in the experimental design used for this study, the Pdia3 pathway was dominant. Taken together, this suggests that Pdia3 and VDR act at different points in osteoblast differentiation and that the relative contributions of the mechanisms are dose-dependent as well as time-dependent.
If Pdia3 action modulates terminal differentiation of MC3T3-E1 cells, we would expect that 1α,25(OH)2D3 would cause an increase in mineralization in Sh-Pdia3 cells but a decrease in Ov-Pdia3 cells. Both of the transfected cell lines exhibited fewer von Kossa positive nodules when cultured in growth media than were seen in wild type cells, related at least in part to the reduced levels of viable cells in these cultures. In osteogenic media, however, we observed more von Kossa positive nodules in Sh-Pdia3 cultures and fewer nodules in Ov-Pdia3 cultures compared to wild type MC3T3-E1 cells and this was matched by corresponding differences in alizarin red positive nodules. Pulse treatment with 1α,25(OH)2D3 had no effect on nodule number in cultures of wild type or Ov-Pdia3 cells, whether determined as a function of calcium (alizarin red) or phosphate (von Kossa). In contrast, pulse treatment of the Sh-Pdia3 cultures with osteogenic media containing 1α,25(OH)2D3 reduced the number of von Kossa positive nodules without affecting the number of alizarin red positive nodules. von Kossa staining detects phosphate, which is produced by the action of alkaline phosphatase. Both wild type and Sh-Pdia3 cells exhibited increased ALP expression when pulse treated with 1α,25(OH)2D3, but only the Sh-Pdia3 cultures had increased von Kossa nodule formulation when grown in osteogenic media containing 1α,25(OH)2D3. These results support the hypothesis that Pdia3 acts in a dose-dependent manner and its actions vary with cell differentiation. The 1α,25(OH)2D3 content of the osteogenic media was determined by the content of the secosteroid in FBS, approximately 10^-12M (48). When differentiated osteoblasts were pulsed with exogenous 1α,25(OH)2D3, thereby increasing the concentration, the effect of the secosteroid was to reduce phosphate content, but without impacting Ca++. This was more pronounced in the Sh-Pdia3 cultures, in part due to the reduction in viable cells. In conclusion, our data suggest that in MC3T3-E1 cells, Pdia3 and its rapid membrane signaling decrease mineralization and by silencing Pdia3 mineralization could be largely augmented.

Considering the multiple cellular functions of Pdia3 when studying the consequence of silencing Pdia3, the effects of other Pdia3 dependent mechanisms must be considered. For example, Pdia3 is a chaperone protein that participates in the folding of N-glycosylated integral membrane proteins (12). Pdia3 also exists in the nucleus and binds with DNA, but the effect of this binding on transcription is still unclear (49). Thus, changing Pdia3 expression levels could result in changing various cellular processes and how much of these side effects contribute to our observation is not known. The observation that inhibitors targeting mediators of the rapid response successfully blocked 1α,25(OH)2D3-stimulated OPN protein, supports the idea that the observed effects in Sh-Pdia3 and Ov-Pdia3 are contributed by the specific role of Pdia3 in the 1α,25(OH)2D3 pathway, rather than side effects.

In conclusion, we mapped out a detailed mechanism of 1α,25(OH)2D3 stimulated rapid response in osteoblasts. The importance of this protein to the mechanism was shown by silencing and overexpressing Pdia3. The function of Pdia3 in the first step of our pathway was demonstrated. By establishing the role of Pdia3 in 1α,25(OH)2D3-dependent gene transcription, protein secretion and mineralization, we showed that the proposed Pdia3 signaling pathway has significant physiological relevance. This conclusion is supported by studies showing that mice with reduced levels of Pdia3 (Pdia3+/-) have a defective bone phenotype (50).

Fig. 4. Effect of 1α,25(OH)2D3, PLAA and AA on PKC activity and effect of 1α,25(OH)2D3 on PGE2 release in wild type, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1 cells. (A): the effect of 1α,25(OH)2D3 on PKC activity of WT, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1 cells. MC3T3-E1 cells were treated with vehicle (ethanol) or 10^-10, 10^-9 or 10^-8M 1α,25(OH)2D3 for 9mins. PKC activity was normalized to total protein. (B): 1α,25(OH)2D3 effect on PGE2 release of WT, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1. MC3T3-E1 cells were treated with vehicle (ethanol) or 10^-10, 10^-9 or 10^-8M 1α,25(OH)2D3 for 30mins. PGE2 in conditioned media was measured and normalized to cell number. (C): PLAA effect on PKC activity of WT, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1 cells. MC3T3-E1 cells were treated with vehicle (ddH2O) or 10^-6, 10^-7 or 10^-8M PLAA for 9mins. PKC activity was measured and normalized to total protein. (D): AA effect on PKC activity of WT, Sh-Pdia3 and Ov-Pdia3 MC3T3-E1 cells. MC3T3-E1 cells were treated with vehicle (media) or 10^-4, 10^-5 or 10^-6M AA for 9mins. PKC activity was measured and normalized to total protein. * p<0.05, treatment vs. control; • p<0.05, 10^-8 and 10^-9 vs. 10^-10; # p<0.05 Sh-Pdia3 and Ov-Pdia3 vs. WT for the same treatment.

Fig. 5. Effect of 1α,25(OH)2D3 on gene transcription in wild type and Sh-Pdia3 MC3T3-E1 cells. Wild type and Sh-Pdia3 cells were treated with vehicle (ethanol) or 10^-8M 1α,25(OH)2D3. After 9mins, media were replaced with fresh media for another 8 hours before harvest. Real-time PCR was performed against twelve bone related genes: (A) osteopontin; (B) alkaline phosphatase; (C) matrix metalloproteinase 13; (D) osteoprotegerin; (E) osteocalcin; (F) Smad2; (G) inositol 1,4,5-trisphosphate 3-kinase A; (H) vitamin D receptor; (I) osteonectin; (J) Runx2; (K) protein disulfide isomerase associated 3; and (L) bone sialoprotein. T/C represents the treatment over control ratio. Absolute values of targeting genes were first normalized by GAPDH. Then the normalized values from treatment groups were further divided by the normalized values from vehicle (ethanol) control groups. * p<0.05, treatment vs. control; # p<0.05, Sh-Pdia3 vs. WT for the same treatment.

Fig. 6. Effect of 1α,25(OH)2D3 on ERK1/2 phosphorylation, OPN secretion and in vitro mineralization in wild type, Sh-Pdia3 and Ov-Pdia3 cells. (A) and (B): Wild type and Sh-Pdia3 MC3T3-E1 cells were treated with vehicle (ethanol) or 10^-8M 1α,25(OH)2D3 for 9mins. The media were replaced and cells were harvested at 0min (no treatment), 30min and 90min after treatment. Intracellular phospho-ERK1/2 was measured by ELISA and normalized to total protein. (C): Wild type, Ov-Pdia3 and Sh-Pdia3 MC3T3-E1 cells were treated with vehicle (ethanol) or 10^-8M 1α,25(OH)2D3 for 9mins with or without 10^-7M quinacrine or 10^-6M BAPTA-AM. After 9mins, the media were replaced and after 24 hours, OPN was measured in the conditioned media using an ELISA assay. OPN levels were normalized to cell number. (D) (E) and (F): Wild type, Ov-Pdia3 and Sh-Pdia3 cells were cultured in growth media or osteogenic media with or without pulse treatments (9 min) with 10^-8M 1α,25(OH)2D3 every 48 hours. Four weeks
after seeding, cultures were examined by alamar blue, alizarin red and van Kossa staining. (D): Number of alizarin red positive nodules; (E): Number of von Kossa positive nodules. (F): Relative fluorescence units of alamar blue stain. Numbers indicate the cell viability. Each data point represents mean ± SEM for N = 6 independent cultures. * p<0.05, 30min and 90mins vs. 0 mins for A and B or 1α,25(OH)₂D₃ vs. vehicle (ethanol) for C or OM± 1α,25(OH)₂D₃ vs. GM for D, E and F; • p<0.05, OM+1α,25(OH)₂D₃ vs. OM-1α,25(OH)₂D₃ for D, E and F; # p<0.05, 1α,25(OH)₂D₃ vs. vehicle (ethanol) for A and B or Sh-Pdia3, Ov-Pdia3 and WT with inhibitors vs. WT for the same conditions for C, D, E and F.
