Flavonoids, a group of natural compounds found in a variety of vegetables and herbal medicines, have been intensively reported on their estrogen-like activities and particularly their ability to affect bone metabolism. Here, different sub-classes of flavonoids were screened for their osteogenic properties by measuring alkaline phosphatase (ALP) activity in cultured rat osteoblasts. The flavone baicalin derived mainly from the roots of Scutellaria baicalensis showed the strongest induction of ALP activity. In cultured osteoblasts, application of baicalin increased significantly the osteoblastic mineralization and the levels of mRNAs encoding the bone differentiation markers, including osteonectin, osteocalcin and collagen type 1 α 1. Interestingly, the osteogenic effect of baicalin was not mediated by its estrogenic activity. In contrast, baicalin promoted osteoblastic differentiation via the activation of Wnt/β-catenin signaling pathway: the activation resulted in the phosphorylation of glycogen synthase kinase 3 β and, subsequently, induced the nuclear accumulation of the β-catenin, leading to the transcription activation of Wnt-targeted genes for osteogenesis. The baicalin-induced osteogenic effects were fully abolished by DKK-1, a blocker of Wnt/β-catenin receptor. Moreover, baicalin also enhanced the mRNA expression of osteoprotegerin, which could regulate indirectly the activation of osteoclasts. Taken together, our results suggested that baicalin could act via Wnt/β-catenin signaling to promote osteoblastic differentiation. The osteogenic flavonoids could be very useful in finding potential drugs, or food supplements, for treating post-menopausal osteoporosis.

Bone remodeling is an active, dynamic and lifelong process, and which involves the
removal of old bone by osteoclasts and the formation of new bone by osteoblasts. The process is crucial for the maintenance of bone strength and integrity. Osteoporosis, the most common bone remodeling disease results from the imbalance of bone resorption and formation, is most frequently observed in post-menopausal women. The major cause of post-menopausal osteoporosis is the deficiency of estrogen (1). Estrogen is known to control the processes of bone remodeling during reproductive life in women (2, 3), and indeed the deficiency of estrogen has been reported to accelerate bone loss (4). Clinically, estrogen replacement therapy (ERT) is being used to alleviate post-menopausal osteoporosis; however, the adverse effects of long term usage of estrogen (e.g. breast cancer, cardiovascular disease) have hindered the use of such therapy. Together with estrogen, other anti-osteoporosis drugs (e.g. bisphosphonates and calcitonin) are mainly acting as inhibitors of bone resorption (5); the effect of these drugs in increasing or recovering bone mass is limited. It is desirable to have anti-osteoporotic agents, or food supplements, that could stimulate new bone formation and correct the imbalance of trabecular micro-architecture (6, 7). Since new bone formation is primarily a function of osteoblasts, the agents acting by either increasing the proliferation of cells of the osteoblastic lineage or inducing differentiation of the osteoblasts could enhance the bone formation (6). In addition, osteoprotegerin (OPG), a soluble member of the tumor necrosis factor receptor (TNFR) superfamily that is secreted by osteoblastic lineage cells, has been shown to inhibit osteoclastogenesis (8, 9) and to prevent bone loss in rats following ovariectomy (8). Application of estrogen has also been shown to stimulate the production of OPG in estrogen-responsive human osteoblastic cell lines and in normal human osteoblasts (10).

Flavonoids, a group of naturally occurring compounds that are commonly found in variety of vegetables and herbal medicines, have been extensively reported on their ability to affect bone metabolism, and which could be sold as phytoestrogens in the consumer market. Daidzein and genistein, are the subclass of isoflavones mainly from soybeans and their derivative foods, have been determined to reduce the occurrence of osteoporosis (11-13). Genistein is also known to possess inhibitory effect on bone resorption (14, 15). Naringin, a flavonoid that found in citrus fruits has been reported to induce the expression of bone morphogenetic protein-2 via PI3K, Akt, c-Fos/c-jun and AP-1 pathway in osteoblasts (16). Rutin, a glycoside derivative of flavonoid quercetin, was shown to inhibit the ovariectomy-induced osteopenia in female rats (17). The hypothesis has been addressed that flavonoids could be bioactive molecules that could counteract the deleterious effects of estrogen deficiency occurring during woman menopause.

Here, flavonoids of different subclasses were first screened on their abilities to induce osteogenesis by measuring the activity of alkaline phosphatase (ALP), an indicative osteoblast differentiation marker, in cultured osteoblasts derived from newborn rat calvaria.
Our results showed that baicalin, one of the major components isolated from the root of a medicinal herb *Scutellaria baicalensis* Georgi, displayed the strongest stimulatory effect on ALP activity. This flavone was able to stimulate the expression of various bone markers during bone differentiation, including type I collagen (COL1A1), osteonectin, osteocalcin, and which enhanced the mineralization of cultured osteoblasts. Interestingly, this baicalin-induced osteogenic effect was not due to its estrogenic activity. Instead, baicalin promoted osteoblastic differentiation by activating the Wnt/β-catenin signaling pathway via Wnt/LDL receptor-related proteins (LRPs) 5/6, resulting in the phosphorylation of glycogen synthase kinase 3β (GSK3β) and the nuclear accumulation of β-catenin, which subsequently activated the down stream Wnt-targeted gene transcription for osteogenesis. Furthermore, baicalin was also able to regulate the expression of OPG in osteoblasts and thereby possibly had duel effects on the regulation of osteoblast and osteoclast differentiations.

**EXPERIMENTAL PROCEDURES**

*Chemicals and flavonoids*- Baicalin and baicalein were purchased from Wakojunyaku (Osaka, Japan): the purity of both chemicals was over 98%, and which was dissolved in dimethyl sulfoxide (DMSO) to give a stock solution at 100 mM. 17β-Estradiol, vitamin C, dexamethasone, ICI 182,780 and p-nitrophenyl-phosphate (pNPP) were purchased from Sigma (St. Louis, MO). 1,3-Bis-(4-hydroxyphenyl)-4-methyl-5-[4-(2-piperidinylethoxyphenol]-1H-pyrazole dihydrochloride (MPP), (R,R)-5,11-diethyl-5,6,11,12-tetrahydro-2,8-chrysenediol ((R,R)-THC), recombinant human Dickkopf related protein 1 (DKK-1) and recombinant human Wnt-3a were purchased from Tocris Bioscience (UK). All other flavonoids were purchased from National Institute for the Control of Pharmaceutical Biological Products (NICPBP; Beijing, China).

*Cell culture*- Rat primary osteoblasts were cultured and prepared by the method previously described (18) with minor modifications (19). In brief, postnatal day 1 rats were decapitated to collect calvarias. Tissues were sequential digested by 1% trypsin for 10 min, 0.2% collagenase for 20 min and lastly freshly prepared 0.2% collagenase for another 45 min. After the digestion, the supernatant was collected and centrifuged for 5 min at 1,500 rpm. Osteoblastic cells were re-suspended and maintained in modified Eagle’s medium α (MEMα), supplemented with 10% fetal bovine serum, 2 mM L-glutamine, 100 units/ml penicillin, and 100 μg/ml streptomycin in a humidified CO₂ (5%) incubator at 37 °C. Differentiation was induced by the treatment of vitamin C (250 μM) and dexamethasone (20 nM) for 7 days. Reagents for cell cultures were purchased from Invitrogen Technologies (Carlsbad, CA).

*Alkaline phosphatase and mineralization assays*- In drug-treated cultured osteoblasts,
the cultures were collected by lysis buffer containing 0.2% Triton X-100, 1 mM dithiothreitol and 100 mM potassium phosphate buffer (pH 7.8). ALP activity was measured by mixing the cell extract with 5 mM pNPP (Sigma) in a buffer containing 0.1 M glycine, pH 10.4, 1 mM MgCl₂ and 1 mM ZnCl₂ at 37 °C and measured absorbance at 405 nm. In the mineralization analysis, cultured osteoblasts were cultured for 21 days. The treatment of baicalin (50 μM) and baicalein (50 μM) and β-glycerolphosphate (20 ng/ml) were performed in a 3-day interval. After 21 days of culturing, the cells were rinsed with de-ionized water twice and fixed in 70% ice-cold ethanol for 1 hour at 4 °C. Mineralization assay was performed by using Alizarin red S (Sigma), in which the cells were stained with 4% Alizarin red S for 15 min at room temperature and washed five times with deionized water. The stained cells were then dehydrated with 70% ethanol followed by absolute ethanol. Orange red staining indicated the position and intensity of the calcium deposits. Results were observed with phase contrast microscope at a magnification of 20X. Alizarin red was quantified using a solution of 20% methanol and 10% acetic acid in water. After 15 min, the liquid was transferred to cuvettes and the quantity of Alizarin red was read on a spectrophotometer at 450 nm. The quantity was normalized to protein content as quantified using Bradford’s method in parallel plates.

Real-time quantitative PCR- Total RNA from cultured osteoblasts was isolated by RNAzol®RT reagent (Molecular Research Center, Cincinnati, OH), and 5 μg of RNA was reverse-transcribed by Moloney murine leukemia virus reverse transcriptase (Invitrogen), according to the manufacturer’s instructions. Real-time PCRs of COL1A1, osteonectin, osteocalcin, Runx2, OPG, RANKL and 18S rRNA transcripts were performed on equal amounts of reverse-transcribed products, using SYBR Green Master mix and Rox reference dye, according to the manufacturer’s instruction (Kapa Biosystems, South Africa). The primers were as follows: COL1A1 (5'-TCC TGC CGA TGT CGC TAT C-3' and 5'-CAA GTT CCG GTG TGA CTC GT-3'; NM_053304), osteonectin (5’-GAA GAG ATG GTG GCG GAG-3' and 5’-ACA GGC AGG GGG CAA TGT ATT TG-3'; NM_012656), osteocalcin (5’-TCT CGT CTC ACT CTG CTG G-3' and 5’-GTG GTG CCA TAG ATG CGC T-3'; NM_013414), Runx2 (5’- AAC TTC CTG TGC TCC GTG CT-3' and 5’-GAC TGT TAT GGT CAA GGT GAG G-3’ and 5’- CAA GAG TGT AGA GAG G-3’; OPG (5’- TGC AGA GAG TGT AGA GAG G-3’ and 5’- CAA GGT GTC TTG GTC TCC A-3’; NM_012870.2), RANKL (5’- CTA TGA TGG AAG GTT GGT ATG CGA ACT TGG G -3’; NM_057149.1) and 18S rRNA (5’- GAC TGT TAT GGT CAA GGT GAA-3’ and 5’-GAT AGT CAA GTT CGG TAA CCG TC-3’; NR_003286). The SYBR green signal was detected by a Mx3000p™TM multiplex quantitative PCR machine (Stratagene, La Jolla, CA). The relative levels of transcript expression were quantified by using the ΔΔCt
method (20). The calculation was done by using the Ct value of 18S rRNA to normalize the Ct value of target gene in each sample to obtain the ΔCt value, which then was used to compare among different samples. The PCR products were analyzed by gel electrophoresis, and the specificity of amplification was confirmed by a melting curve.

**DNA construction and transfection-** Three repeats of estrogen responsive elements (ERE: 5’-GGT CAC AGT GAC C-3’) was synthesized as described previously (21, 22), and then subcloned into a promoter-reporter vector pTAL-Luc (Clontech, Mountain View, CA) that has a down stream reporter of firefly luciferase gene; this DNA construct was named as pERE-Luc. The pWRE-Luc (also known as TOPflash) construct was purchased from Upstate Biotechnology (Lake Placid, NY). This construct contains a firefly luciferase under the control of two repeats each containing three copies of the TCF binding site upstream of thymidine kinase minimal promoter. Green fluorescent protein (GFP)-tagged β-catenin construct was a kind gift from Dr. Henderson (University of Sydney, Australia). The human Runx2 promoter construct (namely pRunx2-Luc) was purchased from SwitchGear Genomics (Menlo Park, CA): this construct contains a firefly luciferase under the control of full-length human Runx2 promoter (~1 kb). The DNA constructs containing the WRE (TAC TTT GAG) derived from mouse Runx2 gene, as well as the mutated WRE (TAC TTA GAG), were synthesized and subcloned into a pTA-Luc (Clontech) having a down stream tagged luciferase gene, which were named pWREmRUNX2-Luc and pΔWREmRUNX2-Luc, respectively. Transient transfection of osteoblasts with the cDNA constructs was performed with a Lipofectamine Plus reagent (Invitrogen), according to the manufacturer’s instruction. The transfection efficiency was consistently 20-30% in the osteoblasts culture, as determined by another control plasmid having a β-galactosidase gene under a cytomegalovirus (CMV) enhancer promoter.

**Western blot analysis-** The phosphorylation of estrogen receptor (ER) α (at serine 118) and GSK3β were determined by western blot assay. Cultures of primary osteoblasts were serum-starved for 3 hours prior to the application of flavonoids. After the treatment, the cultures were collected immediately in lysis buffer containing 125 mM Tris-HCl (pH 6.8), 2% SDS, 10% glycerol, 200 mM 2-mercaptoethanol, and the proteins were subjected to SDS-PAGE analysis. After transferring, the membrane was incubated with anti-phospho-ERα-S118 antibody (1: 2000; Upstate, Lake Placid, NY) and anti-total ERα antibody (1: 1000; Upstate) at 4 oC for 12 hours for the protein detection. Phosphorylated and total forms of GSK3β were recognized by anti-phospho-GSK3β and anti-GSK3β antibodies (1:1000; Cell Signaling, Danvers, MA), respectively, at 4 oC for 12 hours. Horseradish peroxidase (HRP)-conjugated anti-rabbit secondary antibody (1:5000; Invitrogen) was then added to the membranes for 1 hour at room
temperature. In the determination of Runx2 protein expression, cultured osteoblasts were treated with baicalin for 48 hours with different doses (0 to 50 μM). The cultures were then collected and homogenized in a lysis buffer containing 10 mM HEPES, pH 7.5, 1 mM EDTA, 1 mM EGTA, 0.5% Triton X-100, 150 mM NaCl, 1 mM PMSF, 10 μg/ml aprotinin, 10 μg/ml leupeptin, 20 μM pepstatin, 1 mM Na₃VO₄ and 5 mM benzamidine HCl, followed by centrifugation at 12,000 x g for 10 min at 4 °C. Thirty μg of protein lysate was subjected to SDS-PAGE and western blotting: the antibody used was 1:500 dilution from Abcam (Cambridge, UK). The immuno-complexes were visualized by the enhanced chemiluminescence (ECL) method (GE, Healthcare). The band intensities, recognized by the antibodies in the ECL film, in control and flavonoid-treated samples were run on the same gel and under strictly standardized ECL conditions. The bands were compared on an image analyzer, using in each case a calibration plot constructed from a parallel gel with serial dilution of one of those samples as to ensure the sub-saturation of the gel exposure.

β-catenin localization assay- Primary osteoblasts were harvested and lysed after transient transfection with GFP-tagged β-catenin and treatment with baicalin. The nuclear fraction was prepared using the NE-PER nuclear and cytosolic extraction reagents (Thermo Fisher Scientific, Waltham, MA), according to the manufacturer’s protocol. Fifty μl of nuclear lysate, or total cell lysate, per sample was used, and the absorbance reflecting the amount of GFP in each sample was collected in a Tropix TR17 microplate machine. The recognition of histone-1 by antibody (1:1000; Santa Cruz Biotechnology, Santa Cruz, CA) served as a control for the enrichment of nuclear fraction.

Other assays- Luciferase assay was performed by a commercial kit (Tropix Inc., Bedford, MA). In brief, cell cultures were washed with PBS and re-suspended in 100 mM potassium phosphate buffer (pH 7.8) containing 0.2% Triton X-100 and 1 mM dithiothreitol. Forty μl of lysate per sample was used in luciferase assay. The luminescent reaction was quantified in a Tropix TR717 microplate luminometer, and the activity was expressed as absorbance (up to 560 nm) per mg of protein. Protein concentrations were measured routinely by Bradford’s method (23) with a kit from Bio-Rad Laboratories (Hercules, CA). Statistical tests were done by using one-way analysis of variance (ANOVA), where significant changes were classified as * for p<0.05, ** for p<0.01 and *** for p<0.001.

RESULTS

Flavonoids induce the differentiation of cultured osteoblasts. Primary cultured osteoblasts were directly isolated from the calvariae of postnatal day 1 rats. The cultured osteoblasts were capable to undergo differentiation upon the application of the differentiation inducers (dexamethasone and
vitamin C) as represented by (i) an increase of ALP activity (Fig. 1A); and (ii) increase expressions of bone markers, including COL1A1, osteonectin and osteocalcin (Fig. 1B). To determine the stimulating effect of flavonoids in promoting the osteoblastic differentiation, the cultured osteoblasts were treated with different flavonoids. These flavonoids, covering the majority of different subclasses, are predominantly derived from natural foods, vegetables and herbal medicines. The activity of ALP, a well recognized biochemical marker of differentiated osteoblasts, was measured, as shown in Table 1. Over half of the tested flavonoids exhibited an elevated ALP activity in a range from an increase of 10 to 50%. The subclasses of flavonoid, including flavanone, flavone and isoflavone showed the induction effect. The induction over 30% included alpinetin that derived mainly from Alpinia katsumadai, prantensein that derived mainly from Trifolium pretense, and hyperin that derived mainly from Hypericum perforatum. The flavone, baicalin, having the strongest induction of ALP activity, was chosen for further study. Application of baicalin in cultured osteoblasts increased the ALP activity, and the induction effect was comparable to the effect of dexamethasone and vitamin C (Fig. 1A). The application of vitamin C and dexamethasone served as a control differentiation inducer, which increased the expression of differentiation markers by ~4 folds.

The osteogenic effects of baicalin and its aglycone baicalein. There is an aglycone of baicalin, namely baicalein, which does not contain a glucuronic acid at the C7 position on the flavone backbone (Fig. 2A). Although baicalin induced the osteoblastic ALP activity in a dose-dependent manner, baicalein showed no obvious induction effect (Fig. 2B & 2C). In the presence of β-glycerophosphate, the cultured osteoblasts were able to undergo bone mineralization process subjected to 21-day treatment of vitamin C and dexamethasone: thus the nodule was found. The number of nodules observed after the application of baicalin was significantly increased by over 4 folds, as shown in Fig. 2D. In contrast, application of baicalein had limited effect on the mineralization process of cultured osteoblasts (Fig. 2D). Here, both flavones were compared by their activation effects on different reporter constructs (Fig. 3A). Both flavones induced the estrogenic activity by its activation on pERE-Luc transfected osteoblasts in dose- and time-dependent manners (21): the activation was more robust for baicaelein (Fig. 3B & 3C). However, the osteogenic activity was only restricted to baicalin, i.e. baicalein did not affect the transcriptional activity of both pWRE-Luc and pRun2x-Luc transfected osteoblasts, even the concentration of the flavone reached
300 μM (Fig. 3B), or even under 48 hours of
treatment (Fig. 3C). These studies suggested
the structure and function relationship of
baicalin in having the specificity for the
induction of bone differentiation.

**Baicalin-induced osteoblastic differentiation is not mediated by estrogen receptors.**

Estrogen is known to play a significant role
in bone metabolism through the regulation of
bone formation and resorption. Estrogen
receptors (ERs) are the members of the
superfamily of ligand-regulated nuclear
transcription factors. Two ERs have been
identified: ERα and β. Both ERα and β were
found to be expressed in cultured rat
osteoblast (Fig. 4A). The estrogenic activity
of flavonoids could be determined by its
induction effect on the pERE-Luc (3 x ERE
tagged upstream of a luciferase reporter)
transfected cultured osteoblasts (21, 22).
Application of 17β-estradiol, or baicalin, in
pERE-Luc-expressed osteoblasts induced the
activation of pERE-Luc activity (Fig. 4B) in
osteoblasts. These activities showed the
authenticity of pERE-Luc construct. In
addition, the pre-treatment of ICI 182,780 (an
ER blocker), MPP (a specific antagonist for
ERα) and THC (a specific antagonist for ERβ)
fully abolished the baicalin-induced
pERE-Luc activity (Fig. 4B), which indicated
the role of baicalin in estrogenic activation.

Another line of evidence to support the
estrogenic property of baicalin was its role in
ERα phosphorylation. Fig. 4C shows the
phosphorylation of ERα triggered by baicalin
application in a time-dependent manner,
similar to that of 17β-estradiol. The
application of ICI 182,780 again blocked the
ERα phosphorylation.

To test the correlation of estrogenic effect of
baicalin and its ability in stimulating
osteoblastic differentiation, the cultured
osteoblasts were pre-treated with specific ER
antagonists before the application of baicalin.
As showed in Fig. 4D, the pre-treatment of
ICI 182,780, MPP and THC did not show any
significant effect on the baicalin-induced
ALP activity in cultured osteoblasts, even
though these antagonists could slightly
reduce the induction effect. In addition, the
co-application of baicalin and 17β-estradiol,
both at low doses, did not show any
synergistic effect (Supplementary Figure).

These results suggested that the osteogenic
property of baicalin was not fully due to its
estrogenic properties, if any that should be
very little, and might involve other signal
mechanisms. Therefore, the possible signal
mediated by Wnt/β-catenin was determined
here.

**Baicalin activates the Wnt/β-catenin
signaling in osteoblast.** Wnt/β-catenin
signaling plays an important role in the
induction of bone formation. The major
components involved in this signaling
including the transcripts encoding Wnt3a (a
ligand for Wnt/β-catenin receptor), GSK3β,
β-catenin and DKK-1 were found in our
cultured osteoblasts (Fig. 5A). To reveal the
possible role of Wnt/β-catenin in
baicalin-induced osteoblastic differentiation,
the effect of baicalin on the phosphorylation
of GSK3β was first tested. Lithium chloride (LiCl) is known as the GSK3β inhibitor by inducing the phosphorylation of GSK3β. After 10 min of the treatment, LiCl was able to induce GSK3β phosphorylation in a transient manner (Fig. 5B). Similarly, baicalin was able transiently to induce the phosphorylation of GSK3β: the maximum induction was ~6 folds, as compared to the buffer-treated control (Fig. 5B, lower panel).

The translocation of β-catenin into the nucleus is a critical step in controlling the Wnt/β-catenin signaling. Inside the nucleus, β-catenin acts as a co-activator of TCF/LEF family of DNA binding proteins in regulating the Wnt-mediated target genes for osteogenesis. Here, the amount of β-catenin and its subcellular distribution were examined. A cDNA encoding GFP-tagged β-catenin was transfected into cultured osteoblasts. The transfected cells were treated with LiCl and baicalin for 4 hours, and then the nuclear fraction was isolated. In baicalin-treated osteoblasts, the amount of GFP-β-catenin within nuclear fraction was increased over 2 folds, as compared to the control: the increase was restricted only to the nuclear fraction (Fig. 5C). This nuclear translocation event of β-catenin was further confirmed with the increased expression of β-catenin, recognized by antibody in western blots, in the nuclear fraction shown in Fig. 5D. The identity of isolated fraction was confirmed by the enrichment of histone (a nuclear marker).

DKK-1, a blocker of the Wnt receptors, functions via direct binding to LRP5/6, as such which prevents the binding of Wnt ligands onto its receptors for signal induction. In order to confirm the specificity of baicalin in osteoblasts, the cultures were pre-treated with DKK-1 for one hour before the application of LiCl, or Wnt3a, or baicalin. The phospho-GSK3β, induced by Wnt3a or baicalin, were markedly inhibited after the pre-treatment of DKK-1 (Fig. 6A), indicating that baicalin could act on the Wnt-receptor, similar to that of Wnt3a. In contrast, the LiCl-induced phospho-GSK3β could not be abolished by the pre-treatment of DKK-1.

In addition, the activating effect of baicalin on TCF/LEF-dependent gene transcription was tested by a luciferase reporter pWRE-Luc that contained the binding sites for β-catenin-TCF complex (see Fig. 3A). The application of baicalin increased pWRE-Luc activity in a dose-dependent manner (Fig. 6B): the saturation was reached at ~90 μM of baicalin. Moreover, the baicalin-induced pWRE-Luc activity in the DNA transfected osteoblasts was markedly inhibited by the pre-treatment of DKK-1 in the cultures (Fig. 6B).

**Baicalin-induced osteoblastic proteins via the Wnt/β-catenin signaling.** To determine the role of Wnt/β-catenin signaling in baicalin-induced osteogenesis, the cultured osteoblasts were pre-treated with DKK-1 before the challenge of baicalin. The ALP activity and the expression of different bone markers in these cultures were determined:
the up regulation of bone differentiation markers including ALP, COL1A1, osteonectin and osteocalcin were completely blocked under the pre-treatment of DKK-1 (Fig. 7A & B). This specific blockage further confirmed the baicalin-activated Wnt/β-catenin signaling was via the receptors.

The expression of Runx2, a master transcription factor in controlling the osteoblast differentiation, in cultured osteoblasts was also determined under the treatment of baicalin. Fig. 8A shows the up regulation of Runx2 mRNA in response to baicalin application. The baicalin-induced gene activation was in a dose-dependent manner: the maximal induction was ~6 folds at 90 μM of baicalin. As expected, the induction was markedly blocked by the pre-treatment of DKK-1. Application of baicalin for 48 hours also showed a significantly induction on the expression of Runx2 protein (at ~57 kDa) (Fig. 8B). The effect of baicalin on Runx 2 was further tested by using a reporter construct that contained a luciferase enzyme tagged downstream of WRE derived from the mouse Runx2 gene (Fig. 8C upper panel), a regulatory element responsible for Wnt/β-catenin signaling. In transfected osteoblasts, the WRE-driven enzymatic activity was markedly induced by baicalin. However, this response was abolished fully in the WRE mutated construct, i.e. pΔWREmRUNX2-Luc (Fig. 8C lower panel), which again suggested the specificity of baicalin in directing the expression of Runx2, or even other differentiation markers. Here, we also tested the effects of baicalin in regulating the expression of RANKL and OPG. Both RANKL and OPG are produced by osteoblasts. Bone resorption is dependent on RANKL, the catabolic effects of RANKL would be prevented by OPG and thereby prevents the binding of RANK to RANKL for osteoclast differentiation. The balance of OPG and RANKL could affect bone maturation. A high ratio of OPG/RANKL expression is indicative for bone formation, while a low ratio of that favors the bone resorption. Application of baicalin increased the mRNA expression of OPG in primary cultured osteoblasts in a dose-dependent manner, while the expression of RANKL remained unchanged (Fig. 9A). Here, the ratio of OPG/RANKL expression was ~3, i.e. capability to stimulating bone formation. The induction effect was abolished after the pre-treatment of DKK-1 but not by the estrogen receptor inhibitor ICI 182,780 (Fig. 9B). Again, this baicalin-induced OPG expression could be mediated by the Wnt/β-catenin signaling.

**DISCUSSION**

By assaying the ALP activity in cultured osteoblasts, 36 commonly encountered flavonoids deriving mainly from herbal medicines and vegetables were screened for its osteoblastic activity. Twenty of them showed the ALP induction, and baicalin was the best inducer amongst all of them. The treatment of baicalin increased the ALP
activity, the mRNA expression of bone differentiation markers and the degree of mineralization in cultured osteoblasts. Interestingly, these baicalin-induced effects were not affected by the treatment of ER antagonists, including ICI 182,780, MPP and R, R-THC, which therefore suggested that the classical ER response was not fully involved here for the induced osteoblastic differentiation. In contrast, the baicalin-induced osteoblastogenesis was depending on the Wnt/β-catenin signaling pathway via Wnt receptors (LDL receptor-related proteins 5/6). This notion was supported by the application of baicalin resulted in: (i) the induction of phospho-GSK3β; (ii) the increase of β-catenin nuclear translocation; (iii) the activation of pWRE-Luc and Runx2 expression; and (iv) the effect of baicalin was blocked by DKK-1, a blocker of Wnt/β-catenin receptor. Taken together, our results strongly suggested that baicalin could trigger the Wnt/β-catenin signaling cascade in promoting osteoblastic differentiation.

Drugs for osteoporosis could be divided into two categories: anti-resorptive and anabolic agents. Anti-resorptive agents prevent bone resorption. Anabolic agents stimulate bone growth and formation. The flavone described here could have both functions: the high ratio of OPG/RANKL expression in baicalin-treated osteoblast suggests the capability to stimulate bone formation. The naturally occurring flavonoids have been reported to influence the bone health. Ipriflavone, an isoflavone derivative of plant origin, is the first flavonoid reported to prevent bone loss in post-menopausal women (24). Here, we recommended the usage of baicalin, or its parental herb-Scutallaria Radix, to be another possible drug, or as a form of health food supplement, for osteoporosis treatment or prevention. In China, Scutallaria Radix (the dried root of S. baicalensis) has been employed widely as a traditional medicine for centuries. Baicalin is the major flavone of Scutallaria Radix (~8% of the dry weight) (25), and which is known to have an effect on multiple biological functions, including the ability to inhibit aldose reductase and nitric oxide production (26). Baicalin has also been shown to exert beneficial anti-oxidative efficacies by its ability to modulate reactive oxygen species (27), pro-matrix metalloproteinase, pro-inflammatory cytokines and prostaglandin E2 in leukocytes (28). As shown here, baicalin was shown to have a direct role in inducing the key osteoblastic proteins during osteoblast differentiation, and which, in parallel, was shown to have indirect effect, possibly, in regulating the activity of osteoclast via the induction of OPG expression. Thus, our results motivate us to analyze in more detail the molecular mechanism of the bioactive flavonoids, which includes biological activities and metabolism in humans.

Revealing our current results, baicalin contains at least 2 functions in osteoblast: estrogenic properties via ER and osteogenic properties via Wnt/β-catenin signaling. The dual functions of baicalin could serve a
milestone in developing multi-targeted drugs for osteoporosis, in particular for the menopause women. Estrogen and its receptors are known to play roles in bone formation in humans (29) and in mice (30). Estrogen replacement therapy is one of the current treatments for women who are suffering from osteoporosis; however, this treatment has side effects in clinical evidence. The naturally occurring flavonoids are considered to be possible substitutes for estrogen. Unlike estrogen, flavonoids have been reported not to proliferate the growth of cancer cells (31, 32), and indeed flavonoids have been commonly consumed in humans as health food supplements. Besides the classical ERs (ERα and ERβ), a transmembrane G-protein-coupled receptor (GPR30) has been demonstrated to mediate non-genomic estrogenic signaling (33, 34). This membrane-bound ER was shown to be expressed in osteoblasts, osteocytes and osteoclasts (35) suggesting that its possible functions in bone. However, the involvement of this GPR30-mediated signaling in the baicalin-induced activity, or even for other estrogenic flavonoids, has not been revealed so far in the bone development.

Most of the dietary flavonoids in nature exist in a form of β-glycoside, and in most cases, they are hydrolyzed to their aglycone form in producing effects in the body (36). Indeed, many reports have supported the notion that the aglycone forms of flavonoids have stronger bioactivity than their glycosides in vivo. For example, quercetin, but not its glycoside rutin and quercitrin, was found to prevent H2O2-induced apoptosis in macrophages (37). In parallel, Lin et al. (38) found flavonoids without glycosides exhibited more significant inhibitory effects on LPS-induced NO and prostaglandin E2 production than the respective glycosylated flavonoids via the HO-1 induction. In contrast, a flavonol glycoside isolated from Notoginseng Radix et Rhizoma (root and rhizome of Panax notoginseng) possessed a strong activity in preventing amyloid-β-induced cell death; however, this neuroprotective property of flavonol glycoside required a specific sugar attachment within the main chemical backbone. However, the flavonol backbone by itself did not show any protective effect (39). Apart from absorption and metabolism, the differences in flavonoid structures could also affect their bioactivities significantly. Baicalein had been found to be absorbed from the gastrointestinal tract as its aglycone, which was then restored to the parent drug by glucuronidation in intestine and liver (25). Here, we also compared the bioactivities of baicalin and its aglycone bacalein (5, 6, 7-trihydroxyflavone) by means of estrogenic and osteogenic properties, and which definitely had distinct differences. Baicalein was shown to exert a much stronger estrogenic effect than baicalin by activating the estrogen responsive elements (as shown here), as well as its neuroprotective properties against brain damage (21, 40). However, baicalein showed almost no effect in stimulating the differentiation of osteoblasts. In other words, the stimulatory effect of baicalin on bone differentiation
could be specifically resulting from the additional glucuronic acid at C7 position.

**FIGURE LEGENDS**

Fig. 1. Differentiation of cultured osteoblasts induced by dexamethasone and vitamin C and baicalin. A. Cultured rat osteoblasts were treated with dexamethasone (20 nM) and vitamin C (250 μM) or baicalin (50 μM) for different days. Cell lysates were collected for ALP assay. B. The treatment of the cultures as in (A) for 24 hours. Total RNAs were extracted from cultures to perform quantitative PCR for bone differentiation markers: COL1A1, osteonection and osteocalcin. Control is 0.02% DMSO. Values are expressed as the fold of increase to basal reading (control culture), and are in mean ± SEM, where n=5, each with triplicate samples. *p<0.05; ** p<0.01.

Fig. 2. The stimulatory effect of baicalin and baicalein on osteogenesis in cultured osteoblasts. A. The chemical structure of baicalin and its aglycon baicalein. B. Application of baicalin in cultured osteoblasts for 3 days increased ALP activity in a dose-dependent manner. Application of baicalein for the same period of time did not show induction effect on ALP activity. C. The application of baicalin (50 μM) and baicalein (50 μM) for 3 days. The ALP amount was quantified by histochemical staining. D. Cultured osteoblasts were able to undergo the mineralization upon application of baicalin (50 μM) in the present of β-glycerophosphate (5 mM). After 21 days of the treatment, the stained nodules were found, as shown by Alizarin red staining (upper panel). The degree of mineralization after treatment of baicalein (50 μM) was not obvious. The Alizarin red was quantified using a solution of 20% methanol and 10% acetic acid in water and read on a spectrophotometer at 450 nm.
Fig. 3. Differential activations of different transcriptional responses by baicalin and baicalein. A. The activation effects of baicalin and baicalein on different signaling pathways were tested using different representative reporter constructs. pERE-Luc (three repeats of estrogen response element ERE placed upstream of a firefly luciferase gene) was used to test the effect on estrogen receptor signaling; pWRE-Luc (6 repeats of the Wnt responsive elements (WRE) (T cell factor [TCF] of 5'- GAT CAA A -3') was used to test the effect on Wnt/β-catenin signaling; and a full-length human Runx2 promoter construct named pRunx2-Luc was used to test the effects on osteogenic differentiation. B. Cultured osteoblasts were transiently transfected with three constructs respectively for 24 hours, different doses of baicalin and baicalein were applied for 48 hours, and the cell lysates were collected for luciferase assay. C. Cultured osteoblasts were transiently transfected with three constructs as in (B) and treated with baicalin and baicalein at different time points before collecting for luciferase assay. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where n=5, each with triplicate samples.

Fig. 4. Baicalin-induced osteogenic effect is not mediated by estrogenic activity. A. Total RNAs were extracted from cultured osteoblasts to perform PCR for ERα (510 bp), ERβ (259 bp) by using specific primers. PCR products were resolved on a 1% SYBR stained-agarose gel and visualized under UV light. The identities of PCR products were confirmed by DNA sequencing (not shown). ERα and ERβ cDNAs served as positive controls. GAPDH served as an internal control. Representative images are shown, n=3. B. The construct pERE-Luc was transiently transfected into cultured osteoblasts for 24 hours. 17β-Estradiol (10 nM), or baicalin (50 μM), or pre-treatment with ICI 182,780 (100 nM; ER blocker), MPP (100 nM; ERα antagonist) and R,R-(THC) (100 nM; ERβ antagonist) for 30 min before the applied baicalin. After 2 days, the cell lysates were collected for luciferase activity. C. The treatment was as in (B) but at much short time as indicated. The total and phosphorylated ERα was revealed by antibodies (upper panel). The quantitation from the blots was shown by a densitometer (lower panel). D. The drug treatment was similar to (B) but for 3 days, then ALP activity was determined. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where n=5, each with triplicate samples. * p<0.05.

Fig. 5. Baicalin activates Wnt/β-catenin signaling pathway. A. Total RNAs were extracted from cultured osteoblasts to perform PCR in order to determine the presence of the...
major components in the Wnt/β-catenin pathway including: Wnt3a (435 bp), GSK-3β (356 bp), β-catenin (365 bp) and DKK-1 (148 bp) by using specific primers. PCR products were resolved on a 1% SYBR stained-agarose gel and visualized under UV light. The identities of PCR products were confirmed by DNA sequencing (not shown). GAPDH (657 bp) served as an internal control. Representative images are shown, \( n=3 \).  

B. Baicalin induced the phosphorylation of GSK3β in a time-dependent manner. Baicalin (50 μM), or LiCl (10 mM), was applied onto cultured osteoblasts for different time as indicated. Total GSKβ and or its phosphorylated form (P-GSK3β) (both at ~46 kDa) were revealed by specific antibodies in a western-blot analysis (upper panel). The quantitation from the blots was shown by a densitometer (lower panel). Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO).  

C. The cDNA encoding GFP-tagged β-catenin was transiently transfected into cultured osteoblasts for 2 days. Baicalin (50 μM), or LiCl (10 mM), was applied onto transfected cultures for 4 hours. The cytosolic and nuclear fractions were separated. The total cell lysate (upper panel), or nuclear fraction (lower panel) (both at 50 μl), was subjected to GFP fluorescent determination.  

D. The treatment of baicalin in cultured osteoblasts was as in (C). The nuclear fractions (at 0.5 and 2 hours) were collected for western blot analysis. The levels of β-catenin (~95 kDa) and histone (a nuclear marker at ~32 kDa) were revealed by specific antibodies. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO). In all cases, the values are in Mean ± SEM, \( n=4 \), each with triplicate samples.

**Fig. 6.** DKK-1 blocks baicalin-induced osteoblastic differentiation.  

**A.** Baicalin (50 μM), or Wnt3a (200 ng/ml), or LiCl (10 mM), was applied onto cultured osteoblasts for 10 min, with or without the pre-treatment of DKK-1 (0.2 mg/ml) for 1 hour, as indicated. GSK3β, or its phosphorylated form (P-GSK3β), were revealed (both at ~46 kDa) by specific antibodies by western-blot (upper panel). The quantitation from the blots was shown by a densitometer (lower panel).  

**B.** In pWRE-Luc-transfected cultured osteoblasts, baicalin at different concentrations were applied for 2 days, with or without DKK-1 pre-treatment as in (A). Cell lysates were collected for luciferase assays. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where \( n=5 \), each with triplicate samples. *p<0.05; **p<0.01.

---

**Fig. 7.** Baicalin-induced osteoblastic differentiation is mediated by Wnt/β-catenin signaling.  

**A.** ALP activity was determined after the application of Baicalin (50 μM), Wnt3a (200 ng/ml) or LiCl (10 mM) onto cultured osteoblasts for 3 days, with or without the pre-treatment of DKK-1 (0.2 mg/ml) for 1 hour, as indicated.  

**B.** Total RNAs were extracted from cultures after treatment as in (A) for 2 days to perform quantitative PCR for bone differentiation markers: COL1A1, osteonection and osteocalcin. Values are expressed as the
fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where n=5, each with triplicate samples. ** p<0.01.

**Fig. 8.** Baicalin induces the expression of Runx2 in cultured osteoblasts. A. Baicalin at different concentration was applied onto cultured osteoblasts for 2 days, with or without the pre-treatment of DKK-1 (0.2 mg/ml) for 1 hour. Total RNAs were extracted from cultures to perform quantitative PCR for Run2x mRNA. B. Cultured osteoblasts were treated with baicalin at different doses for 48 hours, as indicated. The expressions of Runx2 (at ~57 kDa) were revealed by specific antibodies in a western blot analysis. Wnt3a (200 ng/ml) served as the positive control. C. Two reporter constructs were used here in the transfected osteoblasts. pWRE<sub>mrRUNX2</sub>-Luc contained a luciferase enzyme tagged down stream of the TCF binding element in responding to Wnt/β-catenin signaling, and pΔWRE<sub>mrRUNX2</sub>-Luc had a mutation on the TCF binding site (upper panel). In the transfected osteoblasts, baicalin (50 μM) was applied for 2 days. The cell lysates were collected for luciferase assays. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where n=5, each with triplicate samples. * p<0.05.

**Fig. 9.** Baicalin induces the expression of OPG. A. Cultured osteoblasts were treated with baicalin (50 μM) for different time periods as indicated. Total RNAs were extracted from the cultures to perform quantitative PCR for the expression of RANKL and OPG mRNAs. B. Cultured osteoblasts were treated with baicalin (50 μM), Wnt3a (200 ng/ml) for 2 days, with or without the pre-treatment of ICI 182,780 (100 nM), or DKK-1 (0.2 mg/ml) for 1 hour, as indicated. Quantitative PCR was performed for the expression of OPG mRNA. Values are expressed as the fold of increase to basal reading (control culture treated with 0.02% DMSO), and are in mean ± SEM, where n=5, each with triplicate samples.

Data are means ± SEM, n = 3-5, each with triplicate samples. The value of SEM is within 5% of the mean, which is not shown for clarity. + to +++ indicate the ranking of the ALP activity. – indicates no effect, i.e. below 10% of the increase. The working concentrations of 17β-estradiol, dexamethasone and vitamin C were 10 nM, 20 nM and 250 nM, respectively. The sub-maximal doses of these drugs were used for comparison. For the tested flavonoids, three concentrations, 0.5, 5 and 50 μM were used. RNFG is corresponding to Radix Notoginseng flavonol glucoside or quercetin 3-O-β-D-xylopyranosyl-β-D-galactopyranoside.

Baicalin, a flavone, induces the differentiation of cultured osteoblasts: an action via the Wnt/β-catenin signaling pathway.

PAGE 27890:

FIGURE 6. DKK-1 blocks baicalin-induced osteoblastic differentiation.

An error was found in Fig. 6A (upper panel) after publication. The gel images of (i) PGSK-3β by LiCl treatment (with and without DKK-1) and (ii) GSK-3β by LiCl treatment (with and without DKK-1) were misplaced due to an error in handling the image processing. The results from four independent experiments, from set 1 to 4, are now shown here for clarification and revision. Here, the drugs including baicalin (50 μM), Wnt3a (200 ng/ml), or LiCl (10 mM) were applied onto cultured osteoblasts for 10 min, with or without the pretreatment of DKK-1 (0.2 mg/ml) for 1 h, as indicated. The total GSK-3β, or its phosphorylated form (P-GSK-3β), was revealed (both at ~46 kDa) by specific antibodies in Western blot (upper panel). The quantification of the blots was performed by a densitometer (lower panel), which was quantified based on the four independent results from set 1 to 4, as shown here. The overall result of Fig. 6A, which was illustrated on p. 27888 (line 11), remained unchanged. Values are expressed as the fold of increase to basal reading (control cultured treated with 0.02% dimethyl sulfoxide) and are means ± S.E. (n = 4). **, p < 0.01.
Baicalin, a flavone, induces the differentiation of cultured osteoblasts: an action via the Wnt/β-catenin signaling
